This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Arsenic, pigmentation of the skin during exhibition of, 565
Arterio sclerosis after syphilis, 309
Association of fellows of the royal college of surgeons, England, the, 372
Association of fellows of the royal college of surgeons, England, the, 633
Asylums board extravagance, alleged, 150
Asylums, county council and the, 678
Asylum medical officers, the status of, 288
Asylum attendant, charge of manslaughter against, 525
Asylum reports, 582
Atkinson, Dr. F. P., some results of influenza, 356
Atrophy, hepatic, 254
Atrophy, progressive muscular, 468
Athill, Dr. Lombe, ovariotomy, 351
Aural affections, ætiology of, Dr. H. M. Jones, 381, 407
Australian Colonies, medical federation in the, 122

B

Bacilli, cholera, 13
Bacteriological institute, 67
Bacterial husbandry, 371
Bakehouses, underground, 405
Bakehouses, insanitary, 606
Baking powder difficulty, a way out of, 179
Bar, before the, 579
Barton, Mr. J. K., death of, 296
Bath workhouse infirmary, the nursing staff of, 658
Bequest, munificient, 248
Bingley, poisoning at, 679
Bradford, death under chloroform at, 404
BRADFORD MEDICO-CHIRURGICAL SOCIETY—
  Disease, intercranial, 197
  Mastoid disease, case of, 491
  Obstruction, intestinal anastomosis for, 308
  Pitting in small-pox, 308
  Salpingo-ovaritis, 308
  Simple fracture, treatment of, 418
  Specimens, 197
  Surgical cases, after treatment of severe, 197
  Tags, anal, 417
Basedow's malady, 258
Baths, warm, 444
Belfast hospital, extension in, 125
Benington, Dr. R. C., a case of tubal gestation, 303
Berlin, medical statistics in, 144
Berlin, health of, 12
Berlin university, a windfall for, 144
Barber's hair-clipper, the, 452
Besant, Mrs., as a Ganges bather, 367
Bicarnis, uterus duplex, 39
Biddle, Mr. D., infectious diseases notification act, 532
Bidwell, Mr. L. A., amputation of the breast for cancer, 383
Billroth, death of professor, 174, 200
Billroth, Prof., 200
Biliary fistula, 309
Birmingham vaccination case, the 183
Birmingham board of guardians, the, 449
Birthday honours, the, 578
Bladder, tumour in, 200
Bladder, tumours in the, 200, 333
Bladder, healing of the ureter in the, 368
Blood pressure, 91
Blow at notification, a, 63
Bodies, foreign, 337
Bolton, death of Mr. G., 131
Bone, circulating library, a, 11
Bone disease, peculiar 363
Bones, suture of the, 670
Book, a popular, 679
Bread, adulteration of, 123
Briggs, Dr., and the war office once more, 397
BRITISH GYNÆCOLOGICAL SOCIETY.—
  Gynæcological question, a, 307
  Specimens, 307
  Uterus, fibromatous, 593
  Uterine appendages, conservative treatment, 593
Brown-Sequard, death of, 374; the late professor, 396
Bruce, death of inspector general Dr. H. A., 554
Brush workers, anthrax infection in, 39
Buchanan, testimonial to Sir G., 605
Bucknill, Sir J. E., F.R.S., 576
Budget, drugs and the, 451
Burglar's therapeutic, a, 474
Burleigh Robinson, Dr. W. J., chronic ovaritis, its origin and treatment, 589
Burton, Mr. W. E., influenza, on the treatment of, 109
Budding anti-vaccinationism, 496
Boycotting extraordinary, 95

C

Cancer and arsenic, 205
Cancer, lesions of the stomach simulating, 565
Cancer of the uterus, Mr. F. B. Jessett, 641
Carbolic acid, poisoning by, 126
Carbolic acid, the sale of, 472
Carcinoma, œsophagi, 337
Carcinoma, 541
Care of the idiot and epileptic, 202
Cardiac affections, treatment of the last stage of, 11
Cardiff, infant mortality at, 290
Carlow county infirmary, the, 399
Casuals, Folkestone and its, 524
Catarrhal phthisis, sea voyages in, Dr. E. S. Thomson, 219
CATHOLIC UNIVERSITY MEDICAL SCHOOL—MEDICAL AND SCIENTIFIC SOCIETY—
  Atresia ani, 198
  Simulated elephantiasis, 198
  Leukæmia, 308, 392,
  Peritonitis, case of fatal 172
  Suprapubic cystotomy, 391
  Suggestion, therapeutics of, 198
Causa honoris, 522
Cellars, damp, 72
Cellar bakeries, 232
Cells, lymph, 229
Certification of midwives, the, 574
Chance, Mr. Arthur, operative treatment of enlarged prostate, the, 3
Chapman, Dr. Paul M., the physics of the circulation, 247
Chelsea, hospital for women, the, 179, 259, 370, 317
Chelsea vestry and the hospital for women, the, 399
Chest wall, chondroma of the, 363
Chemists as prescribers, 496
Chemists, prosecution of, 659
Chemist shops, the management of, 621
Child pernicious anæmia in, 253
Children, rachitis as a cause of hernia in, 476
Children, dental caries and cervical abscess in, 504
Children, the prevention of cruelty to, 607
Chinese leper, the savings of a 549
Chloroform, suicide from, 24
Chloroform deaths, the lay press on, 123
Cholera, artificial immunity against, 650
Cholera, the meteorology of, 500, 671
Cholera, precautions against, 546
Christ's hospital, 77
Christ's hospital in 1877, 355
Chondroma of the chest wall, a, 285
Circulation, the physics of the, Dr. Paul M. Chapman, 247
Circulation, fœtal, 493
Cirrhosis of liver, two cases of biliary, 253
City of Dublin hospital, physiciancy of the, 74
Clamp, funis a, M. Alexander Duke, 7
Clark, Sir Andrew, obscure affections of the lung, 187
Clarke, Dr. E. W., case of appendicitis, 386
Clinical demonstrations, Mr. Jonathan Hutchinson, 325, 507

CLINICAL SOCIETY OF LONDON—
  Abscess, splenic, 414
  Aneurism by anastomosis, a case of, 358
  Annual meeting, 562
  Bowel, perforation of the, 279
  Clinical evening, 224
  Chlorine gas, use of, 563
  Diabetes, pancreatic cyst with, 562
  Diabetic patient, typhoid fever in a, 513
  Epitheliomatous formations, multiple, 167

HYSTERECTOMY BY THE CLAMP OPERATION,

A SPECIAL METHOD FOR ITS PERFORMANCE (WITH CASES). (a)

By JOHN W. TAYLOR, F.R.C.S.,
Surgeon to the Birmingham and Midland Hospital for Women.

THE wire-clamp (or "serre-nœud") operation for hysterectomy appears to have lost much of its interest during recent years The operators of to-day are chiefly concerned with intra-peritoneal methods of stump-treatment or total extirpation of the uterus, and any recommendation of the older operation may perhaps be somewhat out of touch with the spirit of the present time. But every surgeon knows that occasionally—and often when the conditions are worst—the clamp operation is the only treatment available, and the best methods of its performance must therefore still be an object of practical interest.

It is true that all clamp operations are to a certain extent clumsy, and have hitherto been tentative in character, but there is this important difference between the clamp operation for ovariotomy and the one I am now discussing, that whereas the former gave way to a simpler, quicker, and safer method of treatment, it cannot be said, I think, that complete extirpation of the uterus and intra-peritoneal treatment of the stump are either simpler, quicker, or safer than the clamp operation for myoma.

But this depends very much on how the clamp operation is done. The secret of its success depends very largely on the perfect closure of the peritoneum round the stump, and a special way of effecting this I purpose now to consider.

In 1885 (June 6th), after watching several cases of hysterectomy by the clamp operation, I came to the conclusion that this might be both simplified and improved by some important alterations in the usual method of operating. In particular it appeared to me that the temporary rope clamp or elastic ligature was often unnecessarily used, and that a ready means of entirely shutting off the peritoneal cavity from the stump was altogether lost sight of or neglected. I saw that the peritoneal cavity could be absolutely isolated from the stump by *the inclusion of the parietal peritoneum within the wire of the clamp*, and, with this as its essential feature, I then drew upon paper a clamp operation for hysterectomy, which, when practicable, would, I believed, give better results than the methods in usual practice.

For some years I had no opportunity for testing this operation. I had watched many untoward results of hysterectomy for myoma, and had deliberately chosen the removal of the appendages or an expectant treatment (when the patient was nearing the menopause) as the only justifiable methods of treatment for myself. To this as time went on I added the occasional treatment by electrolysis. For a long time I found no real necessity for hysterectomy. Although every case of myoma on which I operated was regarded by me as a possible case for removal of the uterus, I found almost always that by taking pains, by a larger incision, by alteration of the position of the tumour from the vagina, by raising the appendages from below, or as in one case, by temporarily turning the whole tumour outside of the abdomen, the operation of removal of the appendages was to be satisfactorily completed. With the final result of this operation I have been, with but few exceptions, fully satisfied. In some of the cases the convalescence has been a protracted one, the operation being followed by a hæmatocele or local abscess on one or other of the local sites where the removal has been carried out, but only in one case (out of 50 operations) has the patient died.

During recent years, however, I have occasionally met with cases in which the treatment by removal of the appendages was either impracticable or manifestly inadequate—cases too in which no benefit was to be derived from expectant treatment, and in some of these cases (five in number) I have used the operation already roughly described. In each case the operation has been followed by a good and easy recovery, and I think the method I practise presents so many and such plain advantages that it is worthy of more extended use. The operation is done as follows :—

1. The abdomen is opened in the middle line, and the bulk of the tumour is disengaged from the peritoneal cavity and drawn outside the incision in the usual way. After attending to adhesions the position of the appendages, of the bladder, and of the rectum are specially investigated, and if necessary the uterine attachments of the broad ligaments are separated between double ligatures. Unless this is really necessary it is much better to leave the peritoneal covering of the uterus intact.

2. Then the transfixion pins are used, being passed through the peritoneum of the right side of incision, then through the base of the pedicle of the tumour, and finally through the peritoneum of the left side of incision. Two or three of these pins are used, according to the size of the stump. The ends rest upon the skin surface, but the pin does not transfix any part of the incision-edge except the peritoneum.

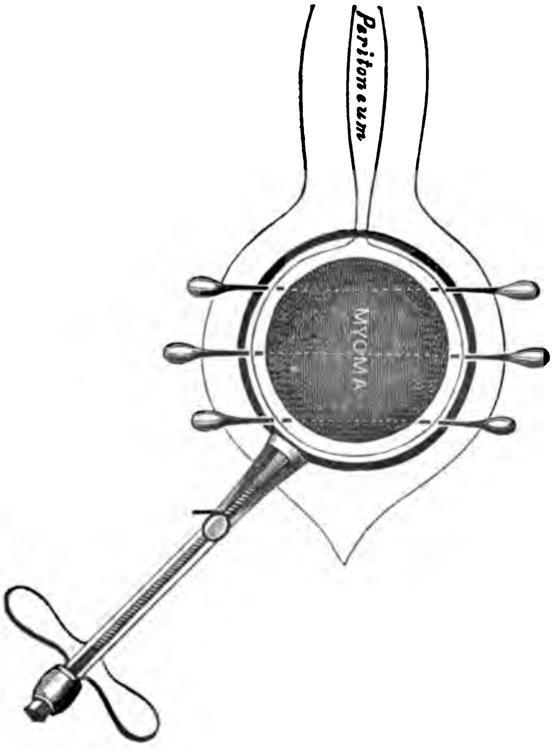
3. The wire clamp is now put on immediately below the pins (and therefore outside the peritoneum). As this is done the opposing edges of the peritoneum immediately above and below the stump are caught together by forceps and the points of these are included in the loop of wire. By this means it is usually easy to arrange that the parietal periosteum is caught up by the wire of the clamp all round the pedicle of the tumour. (When the latter rests just above the pubes and the parietal peritoneum has not been divided too low down, the peritoneum being slightly elastic, can be fitted round the pedicle without forming any lower angle, the only point then which requires special care is that formed by the opposing edges of the peritoneum just above the pedicle.) The clamp is now tightened, the whole of the wire being strictly extra-peritoneal, and compressing the pedicle of the tumour through a single layer of peritoneum throughout the whole of its course.

4. The tumour is cut off. The abdomen and pelvis are carefully cleaned by sponges from the open part of

---

(a) Read before the British Gynæcological Society, Dec. 14th, 1893.

the incision above the stump, the incision is closed and the stump is trimmed and treated with solid perchloride of iron and iodoform.



Sketch of stump with pins and wire of "serre-nœud" in position (diagrammatic). Three pins are depicted in the illustration; two are usually quite sufficient.

Such is the plain description of a simple operation. If a pedicle has to be made by enucleation some kind of temporary compression is necessary before the pins can be passed. In this case I prefer the use of some elastic tubing, believing that this is less likely to injure the vitality of the pedicle than the rope clamp. Unless a temporary clamp is absolutely necessary for special manipulation of the tumour in order to form a pedicle, I much prefer to dispense with its use. It involves waste of time, and may be a source of special danger.

The following cases, given in rough outline, may be cited in illustration of my paper:—

Case 1.—E. S——, single, æt. 46, had suffered for four years from an abdominal tumour which for one year had been growing rapidly. Girth 38½ inches. *Operation*, July 13th, 1892.—Large myoma of uterus. Temporary elastic ligature applied and tumour removed (weight 19¼ lbs.). Two pins used and wire clamp applied immediately below these. The parietal peritoneum was sewn to the stump below the clamp. Clamp separated and removed on August 5th. Recovery and discharge on August 25th. (This was a transitional case in which the wire of the clamp was strictly extraperitoneal, but the parietal peritoneum was united to the pedicle by stitches. These were omitted in succeeding cases.)

Case 2.—E. D——, married, æt. 42, had suffered from a bleeding myoma for several years, and had been operated on by me (in 1890) for removal of the appendages, but only those of the right side could be found. The operation had but little or no effect in restraining hæmorrhage. Second operation, August 30th, 1892. Uterus drawn out of incision. Two pins used transfixing parietal peritoneum on each side as well as pedicle of tumour. Wire clamp applied immediately below these and tumour cut off. Clamp removed on September 10th. Patient discharged on September 27th. Good recovery.

Case 3.—W. E. M——, married, æt. 20. Tumour of abdomen for upwards of a year. Supposed at first to be due to pregnancy. On admission to hospital the case was diagnosed as one of multilocular ovarian cyst. *Operation*, October 29th, 1892.—Large multilocular cyst of left ovary with gelatinous contents which had to some extent escaped into the peritoneal cavity causing peritonitis. The cyst was largely intra-ligamentary, embedded in the pelvis and could not be separated from the uterus. It was enucleated as far as possible and the base of the cyst together with the right horn of the uterus removed by the wire-clamp. Two pins were used passing through the parietal peritoneum on each side as well as the uterus and the wire adjusted immediately below these. The clamp separated and came off on the 13th day. The patient was discharged on December 9th. This patient had some peritonitis on admission, and her general condition for some time after operation was decidedly serious, the pulse rate being especially high (between 120—140). There was no local trouble and the patient made in the end a good recovery.

Case 4.—E. L. L——, single, æt. 41. History of abdominal enlargement for some months. On Sunday May 28th, 1893, was seized with violent pains while out for a walk and had to be brought home in a cab. On examination with Dr. Dudley (May 31st), a prominent, tense, and exquisitely tender tumour was found, filling the abdomen. The tumour was obscurely fluctuant on palpation, the patient constipated and sick. A tentative diagnosis was made of ovarian tumour with twisted pedicle. *Operation*, June 2nd, 1893.—Abdomen found to contain a large fibro-cystic tumour of uterus, at one part inflamed apparently from thrombosis of large veins or venous sinuses near the surface of the tumour. Two pins were passed, transfixing the parietal peritoneum on both sides as well as the base of the tumour, and a wire clamp was adjusted below these. By means of catch forceps above and below, a perfect enclosure of peritoneum was secured and on tightening the clamp the pedicle was entirely ensheathed by the parietal peritoneum. The tumour was then removed (weight 7 lbs.). The clamp was removed on June 16th. The patient was discharged on July 2nd. Good recovery.

Case 5.—S. H., married, æt. 50. History of tumour of the uterus of some years' duration. This had latterly been rapidly increasing in size. On each side of a central tumour of more or less solid consistence was a cystic mass, that on the right side being abdominal, that on the left side pelvic and fixed. These were diagnosed as ovarian cystomata complicating myoma of the uterus, and it was hoped that they might be removed without disturbance of the latter.

Operation Sept. 4, 1893.—Main tumour found to be a soft œdematous myoma of the uterus (or fibro-cystic tumour), one of the nodules on the right side (mistaken for ovarian cystoma), being absolutely cystic. The left ovary was the seat of cystoma, and adherent in the pelvis below the tumour. The right ovary was atrophied. It was necessary to completely turn out the tumour from the abdomen in order to separate the adhesions and remove the ovaries. The removal was a difficult process, and took considerable time, and after this had been completed it was judged wiser to remove the myoma than to return it. The peritoneum of the lower part of the incision was fitted round the pedicle of the tumour (without forming any lower angle), and this with the enclosed pedicle transfixed by two pins. The upper opposing edges of peritoneum were held by forceps while the wire-clamp was adjusted below the pins. The tumour was cut off (weight 4½ lbs.), and after cleaning the peritoneum from the upper part of the incision the latter was closed.

Clamp removed on Sept. 28. Patient discharged to Convalescent Home on Oct. 7. Good recovery.

◆

THE OPERATIVE TREATMENT OF ENLARGED PROSTATE. (a)

By ARTHUR CHANCE, F.R.C.S.I., &c.,

Surgeon in Ordinary to the Lord Lieutenant; Surgeon, Mater Misericordiæ Hospital; Surgeon, Dublin Orthopædic Hospital; Examiner in Surgery, Royal College of Surgeons, &c.

The frequency of obstructive prostatic enlargement, the harassing character of the disease, and the inadequate nature of its palliative treatment, will, I hope justify me in bringing the subject before you to-night. And that I may have a text to act as a base on which to build my remarks, I will read to you brief notes of a case in which I performed prostatectomy with a fair measure of success.

My patient was a worn-looking farm labourer, æt. 56. Save for an occasional cold, the result of exposure, he had had no serious illness, and prior to Sept. 1891 he had never suffered from any form of genito-urinary disorder. At that time he noticed a gradually increasing difficulty in making water. Micturition became more frequent, the stream was weaker and pain was felt over the pubes. Defæcation too was accomplished with much straining, and the motions were flattened.

In February, 1892, these symptoms culminated in an attack of complete retention, and for this condition he was first admitted to the "Mater."

On examining through the rectum the prostate was found to be very large; so much so that it was difficult to pass the finger into the bowel. The growth was of elastic hardness, resembling to the touch solid india-rubber.

After catheterism and other appropriate treatment had been adopted for some days, the power of voluntary micturition returned. But the act was still difficult, painful, and very frequent.

With the idea of reducing the hypertrophy I determined to try the effect of electrolysis. I therefore had a curved trocar made, insulated save for about half an inch at its point. After emptying the bowels, washing out the rectum with an antiseptic solution, and dilating the sphincter, I introduced the point of the trocar well into the prostatic mass. On account of the size and fixity of the growth this procedure was easy; but it was accompanied by free hæmorrhage. Connecting the trocar with the negative pole of a Leclanché battery, I completed the current by applying to the inner side of the thigh a large charcoal electrode connected with the positive pole. The current was then permitted to flow for about 15 minutes, when it was for a short time reversed.

This procedure was repeated six times at intervals of from seven to fourteen days.

At the conclusion of this treatment the patient could hold water for about an hour at a time. Pain and straining still continued.

I then lost sight of my patient for some months, when on the 13th December, 1892, he again appeared in a condition much worse than before. He was worn and haggard-looking. The straining had increased, although the stream was weaker, the pain was worse and the intervals between the acts of micturition were only of about ten minutes duration. To use his own graphic phrases "he hadn't time to warm the bed before he had to get out again," and his distress was so great "that he was praying for a man to come and shoot him." The residual urine was only about two ounces, although the patient thought his bladder nearly full. The water contained neither pus, albumen, nor sugar. Defæcation was still difficult.

On 24th January, 1893, I proceeded to perform suprapubic prostatectomy. The bladder was repeatedly washed out with warm boracic solution and was then as far as possible emptied through a catheter. Subsequently a quantity of about fourteen ounces of boracic solution was introduced by means of a syphon from a vessel held about four feet above the operating table. The penis was then ligatured. No rectal bag was used. As I laid my hand on the relaxed parietes I was surprised to find how thoroughly the bladder was brought into contact with the abdominal wall. An incision of about 2½ inches was made, and the bladder exposed. It was seized with a sharp hook, incised to the extent of about an inch and a half, and the edges of the incision were secured by ligatures passed through the bladder wall and held at their free ends by an assistant. The inner surface of the bladder seemed healthy. The prostate projected inwards as a large, hard mass, not unlike the cervix uteri. The bladder was considerably depressed below this ingrowth. The opening of the urethra could not be detected until a sound had been introduced. It was then found at the apex of the cone-shaped projection. I found it difficult to use a scissors effectively for removing the growth. Instead, I used a flushing scoop, connected with an irrigator filled with sterilised hot water. This apparatus I found most satisfactory. Guided by the sound I scooped out a funnel-shaped opening along the track of the urethra. The hæmorrhage was alarming, filling the bladder and being washed out in large clots by the strong stream of water. But it was stopped rather quickly by flushing with hot water. The prostatic tissue was tough and difficult to excavate. It was washed away in small pieces. I think, all told, I removed about half an ounce of the growth. I then passed my finger well into the prostatic urethra and found no obstruction.

The upper portion of the parietal incision was closely sutured, and the bladder stitched to the abdominal wall. No drainage tube was used.

Briefly, the man had not a bad symptom. He commenced to pass water through the urethra on the 20th day after operation and the wound was healed on the 42nd. I showed him at the June meeting of the Academy. He could then hold water for seven hours.

In August he was engaged building hayricks, and when thrusting up the hay from the ground he slightly strained the abdominal cicatrix. There was no hernia, merely a weak spot. I directed him to wear a suitable truss.

On December 2nd, that is more than 10 months after the operation, I again examined him. His health was much improved, and he had no pain or trouble of any kind. He could hold water easily for 10 or 11 hours, and he assured me that for months he had not found it necessary to micturate during the night. After a long night he found it difficult but not impossible to empty his bladder completely at the first effort. It was easier to partially empty it first and a few minutes later to complete the act. He passes a fair-sized stream of less than normal force, without straining. No evidence remained of a weak spot in the line of incision. Difficulty of defæcation still existed but was somewhat diminished.

Some points in this case merit comment. The large prostates which give rise to bladder trouble rarely project into the rectum. In this case, as I have mentioned, there was much straining at stool, and there was even some difficulty in introducing the finger. The large size of the prostate and the extent to which it was fixed in the pelvis forbade the use of a rectal bag during the operation. But, as I have said, a bag was not necessary.

(a) Read before the Surgical Section, Royal Academy of Medicine in Ireland December 8th, 1893.

The "uniform circular projection surrounding the internal orifice of the urethra" as McGill terms the condition found in my case is not an unusual form of prostatic enlargement. Its frequency has been overlooked from the fact that when at a post-mortem examination on such a case the urinary organs are removed from the body, the prostate losing the support of the surrounding tissues does not project into the bladder as it did during life.

The influence of this form of enlargement in causing partial retention of urine is ingeniously compared by McGill to the action of the mitral valve. In the heart when the ventricle contracts the valve is closed. When the bladder forcibly contracts the intravesical pressure squeezes the valve-like sides of the prostatic projection together so as to, more or less, completely close the urethra. When the violent effort to urinate ceases the greater part of the water gradually flows away.

It appears to me that the usual method of estimating the amount of residual urine is open to fallacy.

Does the passage of a catheter in a patient such as mine completely empty the bladder? The expulsive force of the bladder is usually impaired, but apart from this a considerable quantity of urine free from the eye of the catheter must collect round the projecting prostate. Indeed, the condition of the bladder resembles one of these "button-hole," "non-spilling" ink bottles, from which the ink cannot be completely emptied, no matter in what position the bottle may be placed.

Possibly this may be the explanation of the small amount of residual urine drawn off from my patient. Except on some such supposition as this I find it difficult to explain that with only about two ounces of residual urine (as usually estimated), and with no well marked inflammation, micturition could have been so persistently frequent.

I am inclined to attribute the good result following the use of electricity more to the free hæmorrhage than to any electrolitic action.

Three routes have been suggested for getting at the enlarged prostate—the suprapubic, the urethral, and the perineal. That the suprapubic is the most effective is too obvious a proposition to need defence. But without suture of the bladder, and this is impracticable in most cases, suprapubic prostatectomy is open to two disadvantages, inefficient drainage, and a yielding abdominal cicatrix. As regards the first, my opinion is, I know, at variance with that held by many surgeons. But it seems to me that, as the patient lies on his back, the bladder *overflows* rather than drains through the suprapubic wound. No doubt the abdominal viscera compress the bladder so as to minimise its capacity, but a channel must exist between the ureters and the abdominal opening, and this channel, running past the retropubic space, is constantly full of urine. Besides, the raw cavity of the prostate cannot but be unfavourably affected by the lodgment of irritating urine.

McGill held that suprapubic drainage was efficient but in the same paper, in which he formulates this view, he mentions three cases of suppuration in the retropubic space following suprapubic cystotomy.

It may be urged that by using a tube the danger of extravasation is minimised, but as Mr. Treves says:—"There is no object in introducing a tube into the bladder, and the various syphon drainage tubes are delusions and snares. . . . . No drainage tube will prevent the occasional escape of urine into the connective tissue around the incision."

That the suprapubic incision alone does not effectively drain the bladder was well demonstrated by a case I had some time since. My patient was a clergyman on whom I performed suprapubic lithotomy, removing four fairly large stones. It follows that the opening in the bladder was of considerable size. My patient had long been a diabetic, and the disease seemed rekindled by the operation, as for sometime afterwards he had intense thirst and passed large quantities of urine. Yet in spite of all this, for the first eight days every drop of urine came by the urethra.

Having regard to the possibility of a yielding cicatrix, I would deprecate the transverse division of any of the structures forming the abdominal wall. The upper end of the parietal wound should of course be carefully sutured. I cannot but think that the leaving open, for drainage purposes, of a part of the abdominal wound must occasionally result in insecure union.

In my case the exertion caused by lifting bundles of hay seemed to be the exciting cause of the yielding of the cicatrix. But the straining at stool was probably a contributing factor.

It seems to me that perineal drainage is the best way to avoid both the difficulties I have spoken of. It would give efficient drainage, and in this way would facilitate the early closure of the abdominal wound. The perineal opening would also permit of the free exploration of the prostatic urethra and the detection and removal of growths that might not be obvious to the finger introduced from within. In addition, the effect of a large tube in moulding the new prostatic path might be of distinct value.

I would advocate, therefore, the introduction through a median perineal incision of a large flanged drainage tube, such as is used in empyema, but with no side openings save near the inner end. The urine could be caught by a carbolised sponge as in perineal lithotomy. The use of a tube leading directly from the bladder to a vessel outside the bed is open to the objection that such a tube may be readily obstructed either by kinking or by pressure from without.

Of course a perineal section means some added risk, but I think the advantages to be gained outweigh this. The possible formation of a permanent fistula is another difficulty, but Wishard's operation might be relied upon to close this.

Passing to a broader question, has not the time come to advocate the earlier performance of prostatectomy? The obstruction is due to an organised hypertrophy which no palliative treatment will remove. It increases with time, and the symptoms it causes are distinctly progressive. Every day the bladder degenerates and the prospect of success after a radical operation diminishes. Inflammatory changes may occur despite all precautions. Complete retention with subsequent atony may result from but a little indiscretion. And at best is not catheter life a euphemistic name for a peculiarly irksome condition of slavery?

Excluding those whose condition forbids all operative procedure, are we in the remaining cases to adopt palliative measures until they break down, or are we to adopt prostatectomy at the earliest favourable moment after obstructive prostatic enlargement is with certainty diagnosed. It is to solve this question that I ask your aid.

◆

LAMINECTOMY IN CERTAIN CASES OF SPINAL INJURY, WITH NOTES OF A CASE. (*a*)

By THOS. MYLES, M.D., F.R.C.S.I.,

Surgeon to the Richmond Hospital; Member of Council and Professor of Pathology, Royal College of Surgeons; Member of Council, Surgical Section, Royal Academy of Medicine, Ireland.

The terrible consequences following fractures affecting the spinal column have from the earliest days of

---

(*a*) Read before the Section of Surgery, Royal Academy of Medicine in Ireland, Dec. 8, 1893.

surgery stimulated surgeons to make an effort for the relief of these distressing injuries, but it cannot be said that these efforts hitherto have been very successful. So unsuccessful, indeed, in the past had been every attempt to offer surgical relief that until very recently the majority of surgeons, in utter despair of being able to confer any benefit upon their patients, have assumed a position of hopeless despondency and have resigned themselves to seeing their patients either die at once from the effects of these injuries or sink helplessly into a condition of paralysis.

The advances made in brain surgery during the last decade, and the works of Horsley and MacEwen, in connection with spinal tumours and constriction of the cord, have again aroused surgeons to the hope that at least in some cases of spinal injuries a justifiable attempt might be made to relieve a condition that, unrelieved, could only terminate in death or paralysis.

As this branch of surgery is as yet in its infancy, every contribution to the general information has an importance attached to it which is quite irrespective of the insignificance of the contributor, and it is on this ground alone I venture to bring before you tonight not only the notes of one case, but some general observations on a subject of such great interest.

My patient, J. D., æt. 65, a farm labourer, was admitted into the Richmond Hospital on March 25, 1892, suffering from well-marked paraplegia. The history was as follows:—

He had been standing on a donkey-cart loading up potatoes, when from some cause the donkey moved forwards, and he, losing his balance, fell backwards, striking the ground with the back of his head and neck, so that his chin was driven on to his chest with some violence. When his companions went to his assistance they found that he had lost all power in the lower limbs, and at once brought him to the hospital.

On admission he presented all the symptoms of severe shock and collapse; his extremities, however, were warm, his pulse slow and feeble, respirations shallow and hurried, pupils contracted, his mental condition rather dull, but he complained of pain in the neck, increased by movement. On more detailed examination we found that he had completely lost all power of voluntary movement in the lower limbs, his sphincter ani was relaxed, and his bowels had discharged their contents into his clothing; his bladder had lost its power of expulsion. Cutaneous sensibility, however, was present in both lower limbs, in the left lower limb all reflex action was lost, but on the right side he had well-marked ankle clonus and knee-jerk, and on putting the finger into the bowel a vigorous and sustained contraction of the sphincter followed. There was no priapism.

On the following day he was again examined carefully, and we found the following condition present: Motor paralysis of both lower limbs, a vivid red blush existed in both inner malleoli, where they had probably been in contact. Knee-jerk, ankle clonus, and plantar reflexes were now absent on both sides; the right leg and the whole of the right side of the body was anæsthetic as high as the nipple; above that sensibility still existed. Along the whole of the right arm, with the exception of the ulnar area, cutaneous sensibility could be demonstrated. On the left side the leg, the abdomen, and the lower part of the thorax were anæsthetic, but above the 8th dorsal nerve distribution sensation was present; the left arm, left shoulder, and left side of neck were normal as to sensation. He can pronate and supinate the right hand and can flex the right wrist, but cannot flex or extend the fingers.

On the left side, pronation and supination, flexion and extension of both wrists and fingers are lost; pupils are contracted but react to light slightly. Respiration is entirely diaphragmatic, and on every inspiration the lower ribs are powerfully drawn inwards, the intercostal space depressed and the thorax diminishes in all its diameters except the vertical. On expiration this condition is reversed, the thorax expands, the intercostal depression disappears, and the epigastric bulging subsides. He has now well-marked priapism. When asked to grasp anything in the right hand, he performs a curious evolution; by extending his wrist he makes the flexors tense and so grasps the object, much in the same way as a bird retains its hold on a branch of a tree when asleep.

Having carefully considered the case in consultation with my colleagues Mr. Thompson, and the Vice-President of the College, we determined to give the man whatever small chance an operation could afford.

Chloroform was administered, and an incision made from a little below the occiput to the seventh cervical vertebra, the muscles were cleared and the vertebral arches exposed, it was then found that several of them were shattered and their fragments pressing on the cord. The loose fragments were first removed and then the arches of the 4th, 5th, and 6th vertebræ were completely detached by cutting forceps and the dura exposed. As this seemed tense it was opened and the cord examined, no blood could be seen, and the cord seemed healthy so far as it was visible from the wound. As nothing further could be done, the wound was closed and the patient sent back to bed. For a few hours after the operation he seemed to have got some slight relief, but on the next day he began to sink, and died of dyspnœa on the 28th, three days after the accident.

On making a post-mortem examination we found that in addition to the fractures of the vertebral arches already alluded to, there was also present a fracture involving the body of the third cervical vertebra. The cord when examined from the front had the appearance of being slightly bruised, but was by no means in the shattered condition we would have anticipated from the severity of his symptoms. There was very little blood at the seat of fracture, and no displacement of fragments from the body of the vertebra.

I have given the details of this particular case at some length, because it is only by careful analysis of the symptoms that we can hope to separate cases that are absolutely hopeless from those that offer a prospect of relief by operation.

I think we may fairly lay it down as an axiom that in all cases where the cord is actually divided or seriously disorganised by crushing, operation is hopeless, and, on the other hand, those cases in which the cord is compressed only, and its structure not actually disorganised to any serious extent, may be operated on with a reasonable hope of improvement, if not of actual recovery. Obviously, therefore, the first problem offered to us is one of accuracy in diagnosis.

Can we distinguish between those cases in which the functions of the cord are merely in abeyance, from those in which they are utterly destroyed, and upon our power to supply the answer to this question depends the future of surgery in spinal injuries.

The functions of the spinal cord may for all clinical purposes be divided into three heads:—

1. Conduction and co-ordination of motor and vaso-motor impulses.
2. Conduction and co-ordination of sensory impressions.
3. Discharge of various reflex functions.

With reference to the first two of these, the transmission of motor impulses and sensory impressions, both clinical experience and experiments on animals prove that compression of the cord alone is quite capable of completely abolishing them, temporarily, at least.

A case which occurred in Jervis St. Hospital, under the care of my friend, Dr. Cranny, illustrates this. The patient had all the symptoms of severe spinal injury with loss of motion and sensation, but recovered completely after some days, when a partial dislocation in the cervical region was reduced by traction.

Clinical observations also show that a comparatively moderate amount of injury or pressure is sufficient to annihilate all motor functions in the cord, but that sensory phenomena occasionally persist, even in cases where the cord is seriously disorganised.

We are, I think, therefore, justified in inferring that the loss of motor power does not prove that the cord is injured beyond relief, provided that sensation still persists, but that if *complete* loss of sensation occur with complete loss of motor power below the injury, improvement from operative interference can hardly be hoped for.

The third function of the cord, that of manifesting reflex phenomena, is more intricate and more likely to be of guidance to the surgeon. The exact physiology of the reflex functions of the cord is at present in some doubt. Some years ago, when the physiologist divided the spinal cord in a frog, he found that that useful and interesting creature developed the most extraordinary reflex activity, with the details of which you are all familiar, and which I need not now burthen you.

Experiments on the larger animals seemed to confirm the information thus obtained, and straightway the physiologist and neuro-pathologist enunciated the theory "that reflex centres existed in the cord, that these centres were controlled by the brain or medulla under normal circumstances, and that when such control was removed by division of the cord, the centres became capable of developing unusual activity. "For many years this theory was taught by physiologists, biologists, and clinical teachers; duly absorbed by students, and Bastian's voice, the only one raised against it, on the ground that it was unsupported by clinical experience, became as "the voice of one crying in the wilderness."

Thorburn's clinical researches, however, in cases of spinal injury brought help to the solitary Bastian, and completely cut the ground from under the feet of the scientists by demonstrating conclusively *that all reflex functions were abolished below the injury whenever the spinal cord in man was completely divided.*

This was a staggering blow to the experimenters, but they soon developed new theories to meet the assault. Feeling unwilling to part with their cherished tradition, inherited from the original experiment in the frog, they have modified it somewhat, and now offer the choice of two theories to the anxious surgeon looking for light and guidance. According to the first of these theories, it is alleged that there are reflex centres in the spinal cord of man, but that they are easily disorganised, and that when the cord is injured above these delicate structures, they rapidly succumb.

This theory supplies nearly all that is required, and has the additional merit of making it easier for the physiologists at a further stage to deny the existence of any reflex centres in the cord at all.

The alternative theory to this attributes great importance to the cerebellum. It is asserted that the reflex centres exist in the cord, but that they are incapable of independent manifestations of energy, and that they are normally inhabited by impulses reaching them from the brain and stimulated by impulses reaching them from the cerebellum. That, therefore, when the fibres from the brain are injured, the reflexes will be exaggerated, and when those from the cerebellum are injured the reflexes will be diminished.

I mention these theories, not in the belief that they are of the least use from a clinical point of view, but because they are not only illustrative of the intellectual gymnastics which are so popular at the present day, but because they furnish us with a fair illustration of how much benefit the surgeon derives from the labours of the experimentalist in this particular branch of study.

Leaving theories aside, and coming to clinical facts, increasing experience has shown that all reflex phenomena below the injury disappear for ever, when the human cord is seriously crushed or actually divided, and on the other hand that the persistence of reflex irritability is sufficient to justify us in inferring that the cord is not hopelessly crushed or divided.

I might sum up this part of my paper by stating the following propositions:—

1. That when after spinal injury paralysis affects both motion and sensation, and is associated with loss of reflex irritability, the cord is hopelessly injured.

2. That when paralysis affects motion only and sensation and reflex phenomena are still present the cord is not injured beyond all hope of relief.

3. That the persistence of reflex phenomena is proof that continuity of the cord is not completely destroyed.

4. That all functions, motor, sensory, and reflex can be lost without the cord presenting to the naked eye very obvious signs of disorganisation.

Analysing these propositions we find that the only cases which hold out hopes to the surgeon are those in which motor paralysis is either incomplete, or if complete is associated with persistence of sensibility and of reflex activity.

In what cases, then, can such phenomena be found? Obviously only in those in which the cord is compressed and, mayhap, bruised or slightly torn.

Now the cord can be compressed in a great variety of ways in spinal injury, and it will be necessary to examine these at some length before we can get a clear comprehension of the conditions which justify, and those which fail to justify, operation. Excluding gunshot wounds and stabs, we find that the violence which fractures the vertebræ, or any part of them, may be inflicted in two ways, either by being directly applied to the back or sides, as in the case of a lad treated in Steevens's Hospital, who when falling from a high tree, struck a large branch near the ground causing fracture, with complete separation and dislocation at the tenth dorsal vertebra, or indirectly, as in the case of a young man who was killed by falling from a horse straight on his head.

When the violence is applied directly, and is so great as to cause actual displacement of the vertebral segments, it is obvious that the cord must be hopelessly crushed at the time of the injury, and that operation in such cases is not to be thought of.

When, however, the violence applied to the spine is not so severe as this, a part of the energy will be expended on the muscles and ligaments of the spine and the remainder, though sufficient to fracture the neural arches, and thus compress, bruise, or tear the cord, may at the same time be insufficient to produce complete disorganisation, and thus leave a condition offering some hope of relief by surgical interference.

On the other hand, when the spinal column is fractured as the result of violence, indirectly applied, as in the case of a man diving into shallow water, or falling from a height on his head, in nearly all such cases we find that the cord is seriously injured, and that, too, in a manner that offers but little hope of relief by surgery.

The reason of the hopelessness is easily understood when we analyse the mechanism of such injuries.

When the spine is broken by force applied in the direction of its long axis, such force tends to increase the normal curves in the spinal column, and thus to diminish its vertical height. When the curves are thus forcibly increased we find that two very opposite conditions are produced in the spine.

Along the concavity of the curve the bony tissues will be forcibly compressed, while along the convexity of the curve they will be in the condition engineers speak of, as "tension," or to put it in another way, the tissues in the concavity will tend to approximate those in the convexity to separate. The result of this is that any fragments of bone that may be separated will be forcibly impelled from the front when the pressure is positive, to the back when the pressure is negative, and thus become embedded in the cord. In this way the most terrible injury may be done to the cord without any external disfigurement being present to mark its occurrence.

Moreover, the effects of these injuries are not amenable to surgical relief for two reasons. First, because the cord is at once divided by the jagged fragments, propelled against it with such terrible force, and consequently the removal of the fragments will not restore the functions of the injured organ. Secondly, because the fragments are in the anterior aspect of the cord, and any operation for their removal must necessarily be a very extensive one, and involve very free handling of that delicate organ, so that on the whole I think it may be laid down as an axiom that when the spinal fracture is due to indirect violence causing forcible flexion of the spine, any operation is to be condemmed unless the paralytic phenomena are of a mild type.

I may now sum up by offering the following proposition for debate :—

1. That in certain cases of spinal fracture an operation may be attempted with reasonable hope of benefit.
2. That those cases are alone likely to be successfully treated by operation in which the cord is not completely crushed or divided.
3. That the existence of motor paralysis alone is not proof of hopeless injury to the cord.
4. That the persistence of sensation shows that the cord is not hopelessly injured, even though motor palsy be present.
5. That the complete permanent absence of all reflex phenomena is proof that the cord is hopelessly damaged.
6. That where the symptoms are caused by indirect violence applied to the spine, as a general rule operation is not to be thought of.
7. That where the symptoms are caused by direct violence the propriety of operating depends upon the severity of the injuries and accompanying symptoms.
8. That when the injury is caused by direct violence, if the reflexes persist, and if sensory impressions are still appreciated, an operation may be attempted with reasonable hopes of benefiting our patients.
9. That when the symptoms are due to pressure from extravasated blood, operation is to be advised.
10. That the terrible fate awaiting most patients suffering from severe spinal injury justifies even the most hazardous operations if any hope of benefit therefrom can be reasonably entertained.

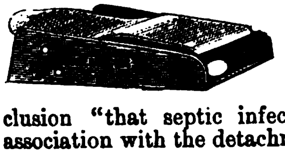
A FUNIS CLAMP.

By ALEXANDER DUKE, F.R.C.S.

The time-honoured plan of ligature and scorched rag as a dressing for the funic stump, I have often considered, could be improved upon, more especially as it is not at all free from risk.



Eröss, from a study of the temperature of 1,000 infants born in the Obstetric Clinic of Buda-Pesth, comes to the conclusion "that septic infection from the navel in association with the detachment of the umbilical cord is a frequent cause of fever, and an important element in the mortality of infants."

Waddington reports two cases (American Medical Association) of "tetanus neonatorum" which began to recover immediately after the application of thorough antisepsis to the granulating protrusion at the umbilicus, evidently caused by absorption from the sloughing cord before separation.

Baginsky declares himself in favour of dry dressing, cotton and iodoform. "Carbolic acid," he states, "is dangerous, for only a slight abrasion of navel is necessary to cause toxic symptoms, as the toxæmia is commonly fatal."

The illustration represents a simple form of clamp, which I consider will be found in use an improvement on the old system. When the infant has been washed, the stump of funis is threaded through the opening in the flat plate of clamp, which lies close to abdomen, while the spring is uplifted by pressure of finger or thumb; the spring is then released, and holds the cord firmly. Anything protruding beyond clamp is cut off with scissors, and the infant's binder and dress put on. The clamp need not be interfered with, dropping off in the usual time with its contents. The small portion of dead tissue it contains is removed, the clamp placed in boiling water, and when dry will be fit for use when next required.

The simplicity and cleanliness of the clamp should give it a preference over the old plan of dressing. The fact of having no dead or dying stump of funis in contact for several days with the infant's abdomen is also a considerable advantage, the scorched rag being anything but reliable in keeping the funis and abdomen from contact. The funis clamp was made for me by Messrs. Arnold and Sons, London, and will be found in practice reliable, cleanly, and efficient, and I hope will prove of much use to every obstetrician.

Cheltenham.

Selected · Prescriptions and Therapeutic Notes.

1. **A Depilatory.**—

℞ Iodi pur. gr. xij ;
Olei terebinthinæ, ♏xx ;
Olei ricini, ʒss ;
Alcohol, ʒijss ;
Collodii, ℥j.

Sig. M. : Apply with a brush once daily for three or four days successively.

Upon the removal of the layer of collodion the hairs will be found also to come away.

2. **Traumatic Tetanus.**—Chloral, seven grains every hour, and four drops of freshly prepared fluid extract of calabar bean every two hours, in a boy of ten years, was followed by recovery after five weeks.—Radcliffe.

3. **Salicylic Acid Ointment in Acute Rheumatism.**—Dr. Bourget (*Medicinische Neuigkeiten*) has made a long series of experiments on the absorption of salicylic acid when employed in the form of a salve in acute articular rheumatism. He simply rubs the joints with the unguent and applies over it a flannel bandage. Out of a large number he has found the following formula the best :—

℞ Salicylic acid,
Lanoline,
Essence of turpentine, ana ʒijss ;
Lard, ℥ijss.
M. *N. Y. Med. Record.*—

4. **Diphtheria.**—Continuous inhalation of the vapour from a mixture of eucalyptus oil, carbolic acid, and turpentine.—Smith.

5.—**Epididymitis.**—For epididymitis, Professor Steer recommends a formula like the following :—

℞ Morph. sulph., gr. j ;
Chloral hydrat, ʒiss ;
Potas. bromid., ʒij ;
Syrup, fʒiv ;
Aquæ, f℥iiss.

Sig. M. : Tablespoonful every three hours, if necessary.—*Med. Fortnightly.*

6. Cancer of the Uterus.—*La Revue Medicale* gives the following formula for a deodoriser :—

℞ Acidi salicylici, gr. vj ;
Sodii salicylat, ʒiij ;
Tr. eucalypti, fʒvj ;
Aq. destill, q.s. ad ℥vj.

Sig. M. : Add three tablespoonfuls to a pint of water, and use as injection every three or four hours.—*Medical Bulletin.*

7. Oxalic Acid as an Emmenagogue.—Parlet strongly recommends oxalic acid for this purpose. He prescribes :—

℞ Acid oxalic, gr. xxx ;
Infusion of tea, f℥vj ;
Syrup of orange-peel, f℥ij.

Sig. M. : Tablespoonful every hour.

It is especially at the expected time of the appearance of the menses that this is indicated. Under these conditions it surpasses all the other emmenagogues of the most reputed.—*Philadelphia Medical Times.*

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, DECEMBER 8TH.

The President, Dr. F. A. NIXON, in the Chair.

THE OPERATIVE TREATMENT OF ENLARGED PROSTATE.

MR. ARTHUR CHANCE read a paper on the operative treatment of enlarged prostate, which will be found in another column.

In the discussion that followed Mr. KENDAL FRANKS congratulated Mr. Chance on the success attending him in this case. He himself had seen this case in the Mater Hospital. He had the satisfaction of knowing from the patient himself that there was a great improvement in his condition. He thought that this operation was one of the many operations that marked the progress of surgery in the latter part of the nineteenth century. They had all met with a great many cases of prostate enlargement, and what a miserable class of cases they were! They knew that after catheter life had been established the patient's life was frequently simply unendurable. They accepted with great pleasure the recommendation of Sir H. Thompson for relieving this miserable condition a few years ago. This method of draining the bladder by the perinæum he had tried in several cases, and he saw that it was certainly a most valuable procedure for giving physiological rest to the bladder, and with relief of all symptoms for a time. But in this operation they had a much more valuable method of dealing with it, because they not only gave physiological rest but they also removed the cause of the disease.

Mr. MYLES thought that this admirable paper presented a subject of the greatest importance and the greatest difficulty. His own experience was that the diagnosis of these cases was not at all simple. He instanced a case sent from the country as one of prostate enlargement. The patient had all the ordinary symptoms, as difficulty of micturition, and on examination per rectum the prostate was found enlarged. All the ordinary catheters got stuck at the bladder, but a short-beaked staff entered. The patient subsequently died, and his bladder was found to be absolutely normal; so that he thought it was a very difficult matter to know what cases of prostate enlargement were cases for operation. Another point of great importance in these cases was the fact that the tenure of life in these patients was extremely limited. He instanced the patient already referred to, who, three hours after the instrument was passed, got a severe rigor, which was repeated, and he died at ten o'clock that night. On examination, all the organs were healthy save the kidneys, which were in a state of hydronephrosis. He said, therefore, that if a man with an enlarged prostate should die after examining the bladder, how much more likely was he to die if he submitted to operation.

Mr. CHANCE, in reply to Mr. Franks, said with regard to the closing of the bladder, that the probability of failure would be very much diminished if perinæal drainage were employed, because there would then be no strain on the bladder. With regard to the time of the operation, when there was obstructive prostatic enlargement, he did not see the use of wasting time, but would deal with it at once. He admitted with Mr. Myles that the difficulty of diagnosis was great, but he always adopted the precaution of first reducing any inflammation by mild measures, and he thought that after that the age and symptoms, &c., would lead them to a right conclusion.

LAMINECTOMY IN SPINAL INJURIES.

Mr. T. MYLES read notes of a case, which we publish *in extenso*, in which a man who had been admitted to the Richmond Hospital for paraplegia, the result of a fall from a cart on the back of his head, had been operated on by him.

Referring to this case, Dr. F. A. NIXON said that through the courtesy of Mr. Myles he had an opportunity of seeing the case. The operation was performed with great manipulative skill, and the cord on exposure seemed to him to be intact and surrounded by its normal coverings. The difficulty, of course, in such cases as this, was to make out accurately to what extent the spine had been injured by the original accident. Apart from that, the great severity of the operation, which required deep incisions, and the removal of the laminæ in cases of spinal injuries, does not seem to favour surgical interference.

Dr. DOYLE mentioned the case of a child, five and a half years old, whom he operated on. She came into hospital suffering from paralysis, increased tendon reflexes, rigid muscles and cystitis. After removing portions of the vertebræ, which were exhibited at the Section last year, there was a temporary improvement for a few days. As this did not continue, he suspected abscess formation causing compression of the cord. He had no difficulty in letting out the abscess, but experienced a great amount in keeping it open, and the child died six weeks after from cystitis and renal trouble.

Mr. KENDAL FRANKS said that laminectomy was an operation not likely to appeal to their experience, because they were not often called upon to operate in cases of spinal fracture. Mr. Myles was to be congratulated on attempting the operation, and he thought from the history of the case he was perfectly justified in performing it. The most contentious portion of his paper was the physiological one, but it was scarcely the subject for discussion in a surgical meeting. He did not agree with Mr. Myles in his agnosticism regarding the physiology of the spinal cord. He thought his disbelief in the physiology of the reflex centres unusually heretical. With regard to the surgical aspect of the question, he thought Mr. Myles acted very properly in removing the long portions pressing in upon the spinal cord, but he did not tell them what the appearances were before he opened the investing sheath. The point of surgical importance was why he opened it? In cases of laminectomy for spinal disease the dura mater should not be opened unless absolutely necessary. That had been laid down by Mr. Victor Horsley. He (Mr. Franks) had done laminectomy for spinal diseases, and he thought it a very valuable operation in suitable cases. He asked Mr. Myles what reasons he had for opening the sheath. He had no doubt that if the theca was found to be bulging from pressure under it, Mr. Myles was perfectly right in opening it; but if the pressure were due alone to fragments of bone pressing on the outside of the sheath, that was a different matter. In conclusion, he said the paper although heretical, was of great importance and interest.

Dr. J. BARTON inquired as to the condition of the cord on making a *post-mortem*.

Mr. Myles, in reply to Mr. Barton, said that no microscopic examination had been made owing to the specimen having been mislaid. The cord had the appearance of being slightly bruised and flattened, but its continuity did not appear to be disturbed. He joined issue with Mr. Franks that the discussion of the physiology of reflex acts at a surgical meeting was inappropriate. He thought that anything which contributes to the accuracy of diagnosis was part of the surgeon's armament. If the frog in his gyrations gave them certain information, they should not be above receiving it. They should not accept any haphazard experiments without comparing them with their own clinical results. As far as his own experience went, all independent reflex action of the spinal cord existed only in the imagination of the physiologist. Then as to the appearance of the spinal cord, he was only familiar with its appearance in the cadaver. However, the dura mater seemed both to his colleagues and himself, and to Dr. Nixon, more prominent than it ought to be, and when pressed upon it gave a sense of fluctuation ; and as the phenomena outside was insufficient to account for the paralysis, it was resolved to puncture lest there might be any possible compression from blood, &c. He had hoped the physiologists would be present, as he thought they might enlighten them regarding the process of evolution which the physiology of the spinal cord was undergoing at present.

The Section then adjourned.

◆

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held December 14th.

The President, Mr. Bowreman Jessett, F.R.C.S., in the Chair.

The President referred in sympathetic terms to the loss the Society and profession had sustained by the death of Dr. Edis, and a proposal that a letter of sympathy should be sent to Mrs. Edis was silently agreed to. He also read a letter of thanks received from Lady Clark in reply to the vote and letter of sympathy by the Society.

SPECIMENS.

Dr. Purcell showed the body, neck, and remains of the os of a uterus, brought away by means of perchloride of zinc. The patient, æt. 44, the mother of eight children, had suffered from pain and hæmorrhage for some time : no loss of flesh. On examination a hard nodular mass was found in the cervix, and implicating the broad ligament. Hysterectomy being excluded the cervix was dredged, dried, and plugged with cotton wool, soaked in chloride of zinc. A cap of india-rubber was placed over the plugs and secured by two transverse silk sutures. On the 13th day the body of the uterus came away. No pain. Patient made a good recovery with command over bladder and rectum, and normal temperature.

Pathologist's Report, by Mr. Plummer.—The specimen consists of almost the entire uterus, with orifices of Fallopian tubes and os uteri. It measures 3¼ inches from fundus to extremity of cervix, and 1¾ inches wide at lower, and 2¼ inches at upper, part. Its weight is 3¼ oz. A piece taken out of the posterior wall and examined microscopically shows healthy uterine tissue with masses of sarcoma cells invading it, with some hæmorrhage. In that particular part the line of the slough seems to have gone through healthy tissue, and thus to have got clear of the disease.

Dr. Napier asked as to the exact condition of the specimen – whether the uterine tumour only was removed, or the uterine peritoneum with it. He suggested that the specimen should be referred to the Pathological Committee.

Dr. Heywood Smith asked how the chloride of zinc applied to the cervix alone could affect the whole corpus uteri.

Dr. Routh asked what became of the portion of vaginal tissue affected, and if Dr. Purcell could explain how so large a quantity of tissue came away.

Mr. Jessett said that since the three cases he had reported to the Society he had seen one in which there was carcinoma of cervix. The patient did not object to treatment by caustics but would not submit to supra-vaginal amputation. The patient made a good recovery. It was found that the body of the uterus was left intact, the internal os being closed. He had had much thought as to how to prevent the caustic from affecting the vagina, and had at last hit on the expedient of placing over the tampons an india-rubber cap such as is used to cover over the top of a pipe.

Dr. Purcell, in reply, gave an account of the method of preparing the chloride of lime tampons. There was no peritoneum on the specimen. He could not account for the size of the portion that came away, for the slough did not extend deeper than one inch, as could be seen from the specimen, and the cotton wool with the caustic did not occupy more than three-quarters of a square inch.

Dr. Heywood Smith suggested that the extent of the separated portion might be accounted for by the presence of the india-rubber cap, which, instead of allowing the caustic to escape from the cervix confined it in the cavity and allowed it to affect the body.

Mr. Taylor (Birmingham) showed three specimens :—(1) A cyst of the Fallopian tube, presumably a hydronephros, with a twisted pedicle. After the birth of her first child the patient had suffered from retroversion with sterility for 9 years; and Mr. Taylor then performed Alexander's operation. She became pregnant, and was confined this year. Shortly after she had abdominal pain and a large tumour was found, which was removed by abdominal section. There were only two previous cases recorded of twisting of the pedicle of a hydronephros. (2) Hæmatosalpinx. The patient, æt. 33, single. The vagina was absent. She had a tumour on the right side, in the pelvis, causing pain, which was worse every month. Abdominal section showed that the left appendages, with the left half of the uterus, were absent. The distended right tube was removed. There had been no further trouble nor any distension of the half-uterus ; he thought this seemed to confirm the view that the tubes play a part in menstruation. (3) A double hæmatosalpinx in a case in which there was also an uterine myoma. On one side there was a small nodule pressing the uterine end of the tube of that side.

Dr. Napier said that he understood that before operation there was no uterine distension ; this being so, he did not think that its absence after operation had any special significance. He had recently seen a case at the Chelsea Hospital for Woman, under the care of Dr. Fenton, in which there there was no vagina. After several attempts had been made to form a vagina, the abdomen was opened and a well-marked hæmato-metra was found. The appendages were removed. He would suggest that as Mr. Taylor's specimen was rare and valuable, it should be referred to the Pathological Committee to report upon.

Dr. Bantock said that tubal menstruation occurred abnormally, but not, he thought, normally ; otherwise the tubes would more often be found distended. He agreed with Dr. Napier that the fact that there was no uterine distension after operation was of little weight; as removal of the ovaries would have the same result.

Mr. Taylor briefly replied.

The President showed two cases of carcinoma of the uterus. (1) With this case there was found associated a large cyst of the broad ligament ; the uterus with appendages and cyst complete was removed by vaginal hysterectomy. (2) This was a case of carcinoma of the body at an early stage. Both patients were progressing favourably.

Dr. Purcell congratulated the President on his good results. When a patient, after vaginal hysterectomy, had passed the 4th day, there was very little danger to be apprehended, as long as no important organs had been injured.

Dr. Heywood Smith called attention to a recent article on hysterectomy in the *American Journal of Obstetrics*, in which the writer advised the use of catgut for sutures. He asked if Mr. Jessett had any experience of catgut, and if so, what was his opinion of it?

Dr. Bantock said that catgut was ordinarily absorbed in 12 days ; chromicised gut and silk remained unabsorbed for weeks or months and sometimes gave rise to trouble.

Mr. Jessett, in reply, said that he had found silk the most reliable material, and if the flaps of peritoneum were brought down, the whole of the sutures would come away in a bunch at the end of a fortnight. Of course, if buried, they would not come away; but in that case, they became encysted, as was the case with the pedicle ligature in ovariotomy.

Mr. **Taylor** then read his paper on

HYSTERECTOMY BY THE CLAMP OPERATION,

A Special Method for its Performance, with Cases. This paper, with illustration, will be found in another column.

In the discussion which followed,

Dr. **Bantock** said he was much interested in Mr. Taylor's paper, but the method he advocated seemed to him not free from objections. The important point at which to secure the peritoneum was just above the uterus. His own plan was to seize the two edges of the peritoneum at this point and secure them with sutures. In passing the parietal sutures it was important to avoid picking up the peritoneum. He thought that if Mr. Taylor tried the suture method he would like it, especially because when the abdominal wall were thick it was very difficult to catch up the peritoneum in the way described. Further, with the clamp method there must be some sloughing of the peritoneal edges.

Dr. **Purcell** said there were only comparatively few cases in which the pedicle of a myoma was long enough to allow the stump to be drawn up, and Mr. Taylor had been fortunate in seeing so many. On the accurate apposition of the peritoneal flaps depended the rendering of the operation extra-peritoneal.

Dr. **Christopher Martin** said he had seen several of Mr. Taylor's cases and had assisted at one; he had been struck with the simplicity of the method, and its good results. He thought it better than Dr. Bantock's plan, because in the latter, the security of the peritoneum depended on a single stitch. But Mr. Taylor's procedure would no doubt be difficult in dealing with a very large myoma.

Mr. **Taylor**, in reply, said that the importance of closing the peritoneum was shown by the great care that had been bestowed on this point. He was glad to know of Dr. Bantock's method, but agreed with Dr. Martin's criticism of it. The advantages of his method were:—(1) It was easy and therefore quick. (2) Recovery was rapid. (3) Even a large pedicle could be easily secured. (4) The danger of sepsis in connection with the clamp was minimised and even averted altogether.

LARYNGOLOGICAL SOCIETY OF LONDON.

Meeting held Thursday, Dec. 13th.

Felix Semon, M.D., F.R.C.P., Vice-President, in the Chair.

PERICHONDRITIS.

The following case was exhibited by Mr. **Anthony Bowlby**. R. Z—, æt. 50, a coachman. Disease began with sore throat eight months ago. Lost voice three months ago. Pain in swallowing for several months. Has had slight winter cough for some years, and he has got worse since the throat became affected. Abscess formed over cricoid cartilage three months ago, and burst. History of syphilis twenty-five years ago. At present there is enlargement and thickening of soft tissues over larynx. Enlarged glands in submental and submaxillary regions. Much pus in and about larynx. Epiglottis swollen and ulcerated. Soft red granulating mass on left side of larynx in subglottic region. General swelling of laryngeal mucous membrane with ulceration in parts.

Dr. Scanes Spicer and Dr. Dundas Grant thought that the case was probably tubercular.

SYPHILITIC STENOSIS OF THE LARYNX.

Dr. **Felix Semon** exhibited the following cases.

Case 1.—Mrs. G.—, æt. about 55. Date of primary affection very many years ago. Throat troubles began more than twelve years ago. In 1883 tracheotomy on account of steadily increasing dyspnœa; has worn tube ever since. The arytænoid cartilages were for many years greatly thickened and almost immobile, the glottis reduced to a very small triangle, formed by the internal aspects of the arytænoids and the posterior wall of the larynx, whilst in its anterior three-fourths the vocal cords were seen to lie close to one another. The voice was quite aphonic all these years. Quite recently, *i.e.*, within the last three weeks, without any apparent cause a surprising improvement had taken place in every respect. The glottis had become much larger, the swelling of the arytænoid cartilages had much diminished, and their mobility improved; the previously aphonic voice had regained tone, and there was now a fair prospect that the tube could be ultimately dispensed with.

Case 2.—W. M—, æt. 37, contracted syphilis in 1884. In 1891 tracheotomy had to be performed. On Feb. 10th, 1893, Mr. Stabb performed thyrotomy, excised large quantities of cicatricial tissue, including the right vocal cord and ventricular band, and removed a large piece of the necrosed cricoid cartilage. Quick recovery and remarkable return of voice, but still considerable narrowness of glottis.

Case 3.—T. R. C—, æt. 32, a medical man. Nov. 25th, 1893, patient received a kick against the left half of the larynx whilst playing football. Immediate aphonia, but no pain and no dyspnœa. When seen at 7 p.m. there was enormous œdema of the whole left half of larynx except the epiglottis. Voice quite aphonic, considerable pain on swallowing, no dyspnœa. Expectoration of slightly blood-stained mucus just beginning. No crepitation to be detected. Four leeches to the left half of larynx. Leiter's coil with iced water round neck, sucking of ice. Temperature never went beyond 99° on second day after accident. Next day left half of larynx changed into brilliantly red, tense tumour, the left half of the epiglottis and left pyriform sinus were also enormously swollen and congested. Antiphlogistic treatment continued. Nov. 30th.—Circumference of swelling about the same as on 26th, but colour markedly purple. Still complete aphonia; no dyspnœa. Slight pricking sensations in left half of throat; Leiter's coil continued. Potass. iod. gr. x, ter die. Dec. 4th.—Colour of swelling now very dark blue. Circumference slightly smaller. Sounds can be produced with effort. Left cord in part seen, intensely congested and motionless in middle line. Iodide continued, but coil left off. Dec. 12th.—Steady convalescence. No subjective inconvenience.

STENOSIS OF FAUCES, THE RESULTS OF ULCERATION.

Dr. **Scanes Spicer** brought forward the case of E. M—, æt. 31, a servant. In 1884 patient had a rash and sore throat, followed by hair falling out. Had had throat troubles ever since. In August, 1893, there was ulceration and marked constriction of fauces. Under iodide the ulceration rapidly improved, the stenosis and dysphagia increasing. When seen in the Throat Department at St. Mary's Hospital on Jan. 18th, 1893, the isthmus faucium was so narrowed by adhesions of the anterior faucial pillars to the tongue that the channel would only admit an ordinary lead pencil; it was made out also that the soft palate was perforated, the uvula almost gone,—the soft palate adherent to the posterior pharyngeal wall. There was no existing ulceration to be seen; no difficulty of breathing or marked voice alteration but extreme dysphagia. Shortly aftewards the cicatricial tissue spontaneously and rapidly ulcerated and a good isthmus was reproduced, allowing comfortable swallowing. The patient had remained thus for nine months, but had reappeared on Nov. 28th, complaining that the dysphagia was increasing again; and on examination it was seen that there was much narrowing, the faucial walls being also ulcerated.

OCCLUSION OF POSTERIOR NARIS.

The following case was exhibited by Dr. **Dundas Grant**. —H. M—, æt. 27, had complained of deafness in the right ear three years ago. She had then complete obstruction of the right nostril, which was full of thick mucus. On rhinoscopic examination the right choana was seen to be completely closed by what looked like a uniform cicatrix. It was in all probability congenital. Dr. Grant perforated it by means of a bistoury and inserted an indiarubber tube, which was left *in situ* for three days. Unfortunately this woke up the dormant ear-mischief and she had perforative inflammation, which had, however, left no trace on the drum-membrane. The opening in the choana soon closed on the removal of the tube, and the operation had to be repeated. She soon got accustomed to the introduction, retention and removal of one of Dr. Grant's vulcanite nasal tubes, and the perforation still remained. She had at times worn the tubes as long as a fortnight. She now wore it at night.

CALCULUS OF SOFT PALATE.

Dr. **CHARLES A. PARKER** showed a drawing of the soft palate before removal of the calculus, and the stone itself. W. R—, æt. 29, was first seen on Oct. 17th. When first seen patient complained of great soreness of the throat, especially on swallowing; sharp pain shooting to right ear, and some deafness on the same side. On looking into the mouth, the right side of the soft palate was seen to be very swollen and inflamed, and was bulging forward into the cavity of the mouth, and felt to the touch excessively hard and solid. Just to the right of the base of the uvula was what looked exactly like a dirty sloughing ulcer, extending backwards a considerable way. The right side of the post-nasal space was entirely blocked, and the swelling was pressing against the Eustachian tube. There were some enlarged glands on the right side of the neck. On further examination the apparent ulcer was found to be the free surface of a calculus, the rest being embedded in the substance of the soft palate, lying apparently in a cul-de-sac between the muscular layers. On Oct. 21st, the stone was removed, which, when dry, weighed 54 grains. The case was interesting chiefly from the position of the calculus. Formations of equal size had been reported as occurring in the crypts of the tonsil, but Dr. Parker was not aware of one in this position being on record.

Dr. **SEMON** remarked upon the rarity of such a calculus, of which he had never before seen or heard of an example. He was inclined to support the theory that it had been originally started by some injury to the soft palate, possibly during operation.

Dr. **BALL** suggested that the calculus might originally have been formed in the tonsillar crypt, and might have worked its way along the submucous tissue of the soft palate.

Mr. **LAKE** mentioned the occasional presence of adventitious masses of adenoid tissue in the soft palate, within which it was possible that the concretion might have begun.

Dr. **WILLIAM HILL** asked whether the stone was removed anywhere near the epitonsillar fossa, which was sometimes very large and a potential crypt. If that were not so, he made the suggestion that the calculus had formed around the residuum of an extra-tonsillar abscess, and asked whether there had been any history of quinsy.

Dr. **PARKER**, in reply, pointed out that the stone was nearer to the uvula than the tonsil, and could hardly have worked its way so far inwards. For the same reason it appeared to be unconnected with the epitonsillar fossa. There had been no history of quinsy.

France.

[FROM OUR OWN CORRESPONDENT.

PARIS, Dec. 21st.

TRACTIONS ON THE TONGUE.

AT the last meeting of the Académie de Médecine M. Laborde reported five new cases of recalling to life by his method of drawing on the tongue, they all related to infants. He was asked by M. Lancereaux to explain under what circumstances his method succeeded, for although he admitted that the operation could be efficacious in cases of asphyxia due to a brusque arrest of the respiration, but that he was not so sure that it would be successful in cases of apparent death due to arrest of the heart's action. M. Laborde replied that the "tongue process" succeeds in every case of asphyxia following primary or secondary arrest of the respiration. In every case of apparent death there exists a latent period, during which the excitability of the bulb persists. His method of recalling to life tended to awaken this excitability, and it was that fact which made it superior to every other method generally used, such as flagellation, insufflation, artificial respiration, &c. M. Lancereaux said that he admitted that the operation described by his learned friend could render good service, but he had employed more than once with success another treatment—that of injections of morphia. In a case of convulsions in a child where death was apparent he injected successively a solution of morphine until he arrived at the total amount of one-fifth of a grain, and the respiration became natural, and the child fell into a calm sleep. He supposed that the morphia had abolished the reflex action, which by acting on the bulb, had determined the arrest in respiration. M. Pinard thought that other treatment than that of traction on the tongue had also frequently succeeded. He was unfortunate enough to have failed three times in the three cases he employed the method of his learned colleague. In one case a quarter of an hour had elapsed between the birth and the treatment. The discussion was closed by M. Laborde saying that he was surprised at the misfortune of M. Pinard, as he had operated with success in one case when the child had lain apparently dead one hour and a quarter. In any case, up to the present 64 cases of recall to life by traction on the tongue have been reported, and that was a fact, in his opinion, worthy of being taken into consideration.

INTERMITTENT HYDRONEPHROSIS.

At the meeting of the Société de Chirurgie M. Routier continued the discussion on the treatment of Hydronephrosis. He said that he observed a case of bilateral hydronephrosis in a woman, who several years previously had suffered from what was considered at the time as renal colic, and who was treated sometime afterwards for cystitis by injections of nitrate of silver and washing out of the bladder by a solution of boric acid. Still later, the patient suffered considerably in the region of the right kidney, and symptoms of cystitis recurring in intensity, it was decided on creating a vesico-vaginal fistula, all other treatment having proved abortive. The operation gave no ease to the patient however, or very little. Last year it was remarked that the urine ceased at intervals, to be followed by an abundant flow. The state of the woman demanded active interference when M. Routier was called in. He found on examination that both kidneys were enlarged, and when pressed upon urine flowed through the fistula. Up to that time the urine was clear and limpid, but a few days afterwards it became purulent, and suppurative hydronephrosis was diagnosed. Nephrotomy was performed, giving issue to a quart of pus derived from four abscesses in the left kidney. The patient was greatly relieved, and a month subsequently the vesico-vaginal fistula was closed. The urine continued to flow with more or less intermission for some time.

TREATMENT OF THE LAST STAGE OF CARDIAC AFFECTIONS.

M. Créquy spoke on the above subject, and said that when the œdema became abundant and hard, giving a sort of elephantiasis aspect to the limbs, diuretics and digitalis were of no avail. In such cases tapping by needles or small scarifications was recommended, but he would prefer incising the tissues with the thermo-cautery at a white heat, which in his hands assured a regular and prolonged flow of the serosity.

M. Paul said he was in the habit of making large incisions with the thermo-cautery in such cases, but remarked that they should be always made at the superior and anterior surface of the leg, as if made on the posterior part cicatrisation becomes very difficult if not impossible. The operation was very simple, and but little painful, and had the advantage of not exposing the patient to infection, erysipelas for instance, as has been witnessed after scarification.

Mal de Pott.

M. Courtin related the case of a young man suffering from Pott's disease with a large abscess in the inguinal region. The abscess was aspirated and a quart of pus removed, and large injections of an antiseptic solution made to wash out the cavity. Then a solution of camphorated napthol (napthol b. 1, camphor 2, proof spirit 3) to the amount of ten ounces was introduced, only a third of which was allowed to return. A fortnight subsequently the abscess was tapped again and a similar injection made, and so on every fortnight for six weeks, when all secretion ceased, and the man made a good recovery.

◆

Germany.

[From our own Correspondent.]

Berlin, Dec. 29th.

The Health of Berlin and the Influence of Hygienic Works.

At the meeting of the Medical Society of the 6th inst. Hr. Th. Weyl gave an address on this subject. He first drew attention to the rapid increase in population that had taken place during the last forty to fifty years. At the commencement of the century Berlin only numbered 120,000 to 130,000 inhabitants. About 1835 its population had increase to 200,000, in the year 1861 it was 547,000, in 1867 700,000, in 1873 900,000, in 1877, 1,000,000 was reached. These figures possess a special interest for the reason that the city possesses data as to the number of deaths corresponding to the number of inhabitants from a certain year downwards. On the basis of the medical statistics introduced by Virchow, not only the gross mortality can be determined, but also the mortality at every period of life, and also the mortality from each separate disease, and these numbers furnish an answer to important hygienic questions.

The total mortality of the city has diminished, the water supply has had, however, scarcely any influence in bringing about this desirable result, but the drainage, on the other hand, has had a most important influence. The mortality of all ages has diminished, but the diminution has been the most marked for the lowest ages.

Of 1,000 living there died in Berlin in the census years :—

Age.	1871.	1875.	1880.	1885.	1890.
0—1	589·95	481·12	444·17	321·44	321·09
—5	188·89	174·30	139·24	117·42	107·26
5—10	12·82	13 97	12·15	9·22	6·93
10—15	4·57	4·35	3·90	3·22	2·64
15—20	7·73	5·59	5·01	3·98	3·53
20—25	9·98	7·91	6·63	5·41	4·86
25—30	12·42	9·23	8·72	7·45	6·32
30—35	17·72	11·49	10·79	10·84	7·79
35—40	20·29	13·91	12·19	12·19	10·50
40—45	26·37	15·16	14·46	13·95	12·27
45—50	26·06	19 49	16·42	16·06	14·79
50—55	38·46	23·49	21·33	19·67	18·37
55—60	44·86	27·57	27·14	26·62	25·08

The deaths from tetanus and from dysentery show a marked falling off, as regards the latter especially. This may be due in part to a greater accuracy in diagnosis, but must in considerable measure be due to increased cleanliness.

The table with regard to tuberculosis including scrofula is as follows :—

Age.	1871.	1875.	1880.	1885.	1800.
0—5	3·6	2 6	2·3	2·4	2·2
5—10	0·7	0.6	0·7	0·5	0·4
10—15	0·6	0·5	0·5	0·6	0·5
15—20	2·5	1·8	2·0	1·7	1·4
20—25	3·2	2·8	2 8	2·8	2·3
25—30	4·0	4·0	4·3	4·1	3·3
30—35	5·8	4·8	5·4	5·4	3·8
35—40	6·2	5·4	5 1	5·6	4·8
40—45	7·5	5·4	5·3	5·3	4·5
45—50	6·1	5·7	4·8	5·3	4·1
50—55	8·8	5·3	4·8	4·3	4·2
55—60	9·4	4·4	6·1	5·3	4·2

The diseases included in the above table as comprising the group tuberculosis are scrofula, meningitis, pulmonary, laryngeal, and tracheal phthisis, hæmoptysis, intestinal and mesenteric phthisis. The mortality from phthisis is said not to have diminished since the discovery of the tubercle bacillus. It will be observed that the most remarkable diminution in mortality from phthisis is in infancy, and this is attributed to greater care in the milk supply, and to the avoidance of milk from cows affected with grapes. That tuberculosis is less fatal at all ages now is explained in part by greater cleanliness, and in part to the care taken to prevent the infection being communicated to others.

Another important and interesting table is that relating to carcinoma in women.

Deaths from carcinoma in women per 1,000 at the different ages :—

Age.	1871.	1875.	1880.	1885.	1 90.
30—35	0·26	0·19	0·30	0·33	0·31
35—40	0·57	0·61	0·72	1·0	0·70
40—45	0·75	1·17	1·77	1·52	1·72
45—50	1·08	2·21	2·37	2·35	2·08
50—55	2·19	2·50	2·81	2·83	2·75
55—60	2·24	2·43	3·84	3·49	4·90
60—	3·03	3·63	4·73	4·22	5·14

This table shows a marked increase in the mortality from carcinoma, and no explanation for it is offered, except that it is possible that through greater care and knowledge it is now diagnosed in cases in which some other disease would formerly have been entered as the fatal one.

A particular interesting table, as regards both water and drainage, and also in regard to its ravages almost everywhere, is that relating to typhoid fever. The mortality per 1,000 of population for the census years at different ages will be seen on next page.

The mortality from typhoid fever in Berlin for all classes was, 1854 to 1860, *pro mille* 38·8 ; 1861-70, 30·29 ; 1871-80, 23-05 ; 1881-91, 7·13.

The diminution in the death-rate from this disease is remarkable and cannot be due to accident. A chart shown by the speaker showed that from the date of the commencement of drainage operations in 1876 the lowering

Age.	1871.	1875.	1880.	1885.	1890.
0—5	1·7	0·8	0·2	0·09	0·04
5—10	0·7	0·6	0·3	0·1	0·03
10—15	0·5	0·5	0·3	0·1	0·09
15—20	0·8	1·6	0·5	0·2	0·16
20—25	0·7	1·3	0·7	0·2	0·14
25—30	0·7	0·7	0·4	0·1	0·09
30—35	0·8	0·7	0·5	0·2	0·09
35—40	0·8	0·6	0·4	0·1	0·09
40—45	0·8	0·5	0·4	0·1	0·05
45—50	1·0	0·4	0·3	0·09	0·08
50—55	0·8	0·7	0·1	0·1	0·08
55—60	0·7	0·8	0·3	0·05	0·07

of the mortality from typhoid fever has been constant, so much is this the case that one is almost tempted to regard the mortality from this disease as a standard of the efficiency of the system of drainage. In comparing these figures with those of other cities, however, it is found that there has been a general diminution in the mortality from typhoid fever in all the cities of Germany, and a diminution that does not correspond in all cases to the introduction of a new and improved system of drainage, but in a large number it does correspord with important hygienic changes, and this is particularly the case in Danzig, Munich, Hamburg, and Frankfort a/M.

The author then attempted by comparing the dates of the carrying out of sewage operations in different parts of the city to show its influence on the mortality of the respective areas. The statistics are not complete, but they are sufficiently so to demonstrate that the mortality in any area fell generally after the introduction of a system of drainage into such area.

In radial system (No. 1) the mortality per 1,000 was 40, 45, and after the introduction of the system 34, 27, 23. In regard to the objection that density of population had some influence on the death-rate, inquiry showed that radial system (No. 1) had the densest population in Berlin, but its mortality had declined notwithstanding.

At the close of his paper Hr. Weyl pleads for the establishment of school medical officers, whose duty shall be not only to superintend the hygienic arrangements of the school, but also to interest themselves in a variety of other ways, to which I hope to refer in my next.

◆

Austria.

[FROM OUR OWN CORRESPONDENT]

Vienna, Dec. 29th, 1893

Cholera Bacilli.

Prof. Paltauf drew attention to the demonstration of Kowalsky's discovery of vibrions which he has announced is the assumed cause of cholera. In 1884 Prof. Escherich describes similar vibrions which he considers had no connection with cholera. Prof. Weichselbaum confirmed this opinion, and said that others besides Escherich, as Kirchner, Fürbringer, Lazarus, &c., found them in the bowel of both nostras and Asiatic; sometimes they were found individually, at others in swarms, but they could not be cultivated. He had found such spirilli himself but would not venture to say they had any importance in cholera Asiatica.

Polypi in Cancer.

Prof. Weichselbaum showed part of a bowel taken from a woman, æt. 30, who had had died in Prof. Weinlechner's department. The morbid process seemed to be a diffuse crop of polypi in the large and small bowel, while three carcinomatous growths were found in the large intestine. He remarked that polypi frequently occur in the large bowel after dysentery. The specimen showed every variety, from a small pin-head to the size of a nut. The microscopic appearance revealed the same texture as found in the Lieberkühn crypts. The three carcinomatous growths were situated one above the cæcum, another in the transverse colon, and a third in the rectum. The one in the transverse colon had produced a fatal stenosis. The histological constitution of these growths was adenous. The one in the cæcum he considered was the first information, being larger and more extensive, involving the right lobe of the liver, to which it was adherent. The other two being younger, were either produced by metastasis or infection. He considered all the three to be derived from polypi, because they contained the same structure found in the alveoli, and around the margin of the carcinomatous ulcers polypi could be seen closely adherent.

Prof. Weinlechner next gave the clinical history of the patient as a young woman who had come under his care in whom he discovered a hard tumour in the ileo-cæcal region with two small polypi in the rectum. The stricture at this part was distended by irrigation, which set up peritonitis, and subsequently formed an abscess over Poupart's ligament that again disappeared. Severe phenomena of bowel stenosis caused laparotomy to be performed when several bands of adhesions were found around the several strictures where the carcinoma of the transverse colon was removed, but she died within ten hours afterwards. He considers the great danger is in the examination of these carcinoma. He described other two cases where attempts to relieve the strictures proved fatal.

Decomposition in the Alimentary Canal.

Dr. Singer has recently been experimenting in Prof. Kaposi's clinic and Ludwig's chemical laboratory with the hope of discovering the physiological connection between a catarrh of the bowel with decomposition and skin eruptions, such as acute and chronic urticaria, acne vulgaris, and pruritus senilis, which seem to have a causal nexus, as these are all found to disappear with a reduction of decomposition in the bowel, while they are greatly aggravated by increase of the decomposition. A drug that would act as an alimentary disinfectant will prove a potent healing agent in skin disease. Urticaria is an old example of alimentary disturbance which is always found in proportion to the decomposition or the quantitative increase of sulphuric ether or the elimination of indican in the urine. Singer has obtained excellent results in skin affections by the use of gelatine capsules of menthol (0·6—1·0 gramme *pro die*) without any external application. Feeding, therefore, is an important factor in dermatological treatment.

◆

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Suprapubic Lithotomy.—Mr. **Mackellar** performed suprapubic lithotomy on a boy, æt. 4, who for the last ten months had complained of pain on micturition; for this he had been circumcised three months ago, but without relief; the little patient was often doubled up with pain, which was referred to the penis, and the bowels acted simultaneously with micturition. By sounding and by rectal examination a stone was discovered in the bladder, the calculus was freely movable. The operator made an incision about two inches long, and the bladder when reached was hooked up and opened by an incision just sufficient to admit the finger; the calculus was then removed by means of the finger; it proved to be a flat stone about one inch in diameter and ½ an inch in thickness with rounded edges. The cut edges of the bladder were then sutured to the deeper part of the abdominal incision and a drain inserted. A rectal bag was used during the operation, and before its commencement the bladder was injected with an antiseptic solution. Mr. MacKellar remarked that he sutured the bladder to the abdominal wall in this case because the walls of the viscus were very much thickened, the bladder itself dropping back and having had to be hooked up, and there was a certain amount of deep hæmorrhage.

Suprapubic Lithotomy.—The same surgeon operated on another case of vesical calculus occurring in a boy, æt. 4, who had been ailing for the last four months, having suffered during that time from severe pain on micturition, the motions being loose, and the urine having been stained with bright blood about every other day. The child was sounded under chloroform, and a stone, apparently small, made out. A rectal bag having been introduced into the rectum, and about two ounces of an antiseptic lotion injected into the bladder, an incision about two inches long was made, and the viscus having been reached, it was incised just sufficiently to admit the finger, by means of which a small calculus was removed. The edges of the bladder wound were then brought together by three sutures, these being passed through the muscular coat only of the viscus. The external wound was next washed with perchloride, and the edges sutured. Mr. Mackellar called attention to the bladder wound having been closed by sutures on this occasion, and not, as in the former case, sewn to the edges of the external incision. He had, he said, employed this method in the second case because the coats of the bladder seemed healthy; the viscus itself was not drawn back, and the bleeding from it was trifling.

◆

Prosecution under the Contagious Diseases (Animals) Act.

Glanders.—Messrs. M'Namara and Company, contractors for the horsing of the Government Mails, of Hill Street, Finsbury, were summoned under the Contagious Diseases (Animals) Act for not giving notice within a reasonable time of a case of glanders occurring on their premises. The contention for the prosecution was that, although notice was given it was not sufficiently early, as the condition of the animal showed the disease to be of at least a week's standing. Mr. Rose imposed a fine of 40s. and 10s. costs.

A "Bone Circulating Library."

A novel application of the Library system is in use at the College of Physicians and Surgeons in New York. There is a department called the "Bone Circulating Library." The shelves and cases of the "Library" contain hundreds of human bones of all sizes and forms. The bones, which are numbered and labelled, are in order on the shelves and in the cases, an attendant being always on hand to act in the same capacity as a librarian. It is his duty to keep track of the bones lent, to enter them upon books, and to see that they are returned uninjured. During the day scores of students flock in and out of this department, carrying packages of strange appearance in their hands or sticking out of their pockets. The packages are made up of human bones, which they are returning or taking from this "Bone Circulating Library."

MEDICAL EXPERT WITNESSES.

The recent murder trial in Edinburgh again raises the question, How long will it be before medical expert evidence, given as it is at present, is abolished? Each trial, such as the one just concluded, exhibits the profession to the public in a most unenviable light. Some of these witnesses are no doubt perfectly sincere in their convictions, but it is a most extraordinary thing that the retaining fee, on whichever side it may be, has such a great part in settling what form these convictions are to take. There is little doubt, however, that to many of the witnesses themselves the necessity of regarding the case from the point of view of their side is repugnant, although they have the assurance to conceal it, for were they once known to be thoroughly honest and to state their opinions regardless of consequences, their employment in forensic cases would cease as a matter of course. What we would like to see is the formation of a medical board attached to the court, which could consider the evidence from its medical standpoint, and report to the judge and jury its opinion on the medical aspects of the case and the reasons for this opinion. The report, if need be, might be both a majority and a minority one. The board could be formed of experts the most capable of giving an opinion on the case in question, the expenses to be defrayed in the same manner as the other expenses of the court, regardless of the verdict, Both sides would then be equally represented without the possibility of the unfortunate bias of fees stepping in. Such a board would be especially useful in those troublesome railway cases in which the patient's physician says that his client is much injured and will never perfectly recover, while the railway company's expert swears that there is little the matter with him and that he will get well in a week or two. We are here reminded of a case in which the discomfiture of a medical expert was complete. He had given his evidence with his usual assurance—he was an old hand at it—and had taken a very one-sided view of the case, also as usual. The opposing counsel managed to get an admission from him that he had not tried to see the matter in any other light, and that the one suggested by the opposing side was quite as possible as the view he had at first taken up. The counsel suggested that he might explain his former attitude. The expert replied, "Well, Sir, I admit you have got me in a corner." "I will leave you in that corner, doctor," said the counsel as he sat down, thus rendering the expert's evidence of no value whatsoever. In the Ardlamont trial the judge hardly alluded at all to the medical evidence in his summing-up, which leads to the natural inference that he attached no importance to it; and inasmuch as several surgeons of eminence were engaged on both sides, this disregard of evidence was presumably intentional. What, for instance, could have been more unfortunate than the extreme diversity of opinion which was shown to exist between the medical witnesses for the Crown and those for the defence. It must be admitted that the medical expert for the defence did not defend his thesis at all creditably in his cross-examination. The case itself was and is still a mystery, and we regret to add in all honesty that it was rendered more so by the expert evidence adduced.

◆

MENTAL DISEASE, FORENSIC MEDICINE, AND HYGIENE AS COMPULSORY SUBJECTS OF EDUCATION.

AN esteemed correspondent, commenting upon our recent objurgation on this subject, says: "It is absurd to think that, as the law at present stands, any new-fledged doctor, who probably never saw a lunatic in his life before, can, by a stroke of his pen, deprive that person of his liberty for seven days in England, or for four or three, as the case may be, in Scotland." Strange as it may appear, we are in complete agreement with our correspondent. What, however, is the remedy? Will an attendance of three months at a course of instruction at a lunatic asylum, or at a course of lectures by a lunacy specialist, make the practitioner materially more competent to remit a patient to incarceration? Not at all. Lunacy is a speciality so unexplored and difficult of exploration that three months of such study can render no real knowledge of it to the student, and the practitioner who has paid his money and spent his time in such lunacy study as the Medical Council prescribes will be scarcely the least bit more competent to pronounce upon the diagnosis and prognosis of the malady. Speaking generally on this question, we cannot hesitate to express the opinion that the *rôle* of the general medical practitioner in Lunacy Certification, in Forensic Medical investigations, and in Hygiene, is misconceived by the existing law. The busy practitioner can never hope to give, in any of these matters, an expert opinion upon which the law should act, though he is certainly capable of giving information and opinion as to facts and antecedent conditions which are indispensable to the correct understanding of the case. Therefore the *rôle* of the practitioner should, in any case of doubt, be strictly limited to supplying this necessary assistance to the expert, and the expert psychologist, medical jurist, or hygeist should be called to his assistance to corroborate his opinion whenever any such doubt exists. There are many instances in which a patient is so obviously mad that certification is more or less a matter of form, others in which the cause of death is so manifest that expert post-mortem examinations are quite unnecessary, and others in which the hygienic conditions are so blatant that skilled tests and expert evidence would be wasted. In every case in which the conditions are in doubt the testimony of the practitioner will always be needed, but we are confident that the time is coming when the law will no longer incarcerate a lunatic, or pronounce a responsible verdict as to cause of death, or direct extensive sanitary changes, except upon the opinion of an expert. We beg, moreover, to observe that it is not the function of the General Medical Council to educate experts either in Lunacy, Forensic Medicine, or Hygiene. The Council is charged by the Medical Act to ensure that the qualification held by any registered person is such as "to secure the possession by the persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of the profession." Subjects not essential for the "efficient practice of the profession" are therefore entirely outside their function, however useful they may be as subjects of mental gymnastics or as ornamental qualifications. If the Council considers it desirable to encourage specialities by registering special diplomas in Dentistry, Public Health, or Lunacy, it will, we think, do well to extend the area of its functions in this regard, but it is altogether wrong for it to attempt to impose education in these specialities upon general practitioners, and we are strongly of opinion that, if the matter were contested before the Privy Council or the Courts of Law, it would be decided that, in so doing, the General Medical Council was exceeding its authority.

◆

THE DEATH-RATE OF ILLEGITIMATE CHILDREN.

NOTWITHSTANDING the intellectual and moral advances of modern civilisation, of which England as a nation may justly be proud, yet there are many defective spots over which the veneer is of the thinnest. To take an instance, it is notorious that the death-rate of children, especially in the great cities, is disproportionately great as compared with that of adults. This excessive mortality is, no doubt, in part directly due to the disadvantages attendant on the struggle for existence when carried on amid the sordid surroundings of our densely populated industrial centres. It is further accounted for, to some extent, by the utter ignorance displayed by mothers generally as to the proper feeding of children. As a consequence, infants are fed upon starchy and farinaceous foodstuffs which they are unable to digest, and which act as so much irritant foreign matter in their alimentary canals. Indeed, chronic starvation might be justly entered as the cause of death in very many instances where the certificate is now filled up with some such general term as marasmus, tabes, or rachitis. Another important contributory cause of infant mortality is the indiscriminate use of teething powders, soothing syrups, and the rest of the patent and quack medicines sold for the express purpose of treating children. It may be said, without exaggeration, that the two classes, proprietors of patent foods and of patent medicines, destroy by their united agency a vast number of children annually, not to mention those of the survivors who struggle through childhood to an adult stage of chronic ill-health. Another factor of less importance is the neglect on the part of parents or guardians to obtain proper medical advice and treatment. Failure in that respect, however, can hardly spring from anything but the most inhuman depravity, now that medical advice is to be freely obtained from the network of hospitals, dispensaries, and other charitable medical institutions which pervade the whole country. Then there may be criminal neglect in the care of their offspring on the part of vicious or cruel parents, and many of them have happily been brought to book by Mr. Waugh and his Society for the Prevention of Cruelty to Children. Indeed, the Society in question has drawn public attention to the wrongs of children with results of a most practical kind, not only as regards the administration and interpretation of existing law, but also as an *in terrorem* warning to all evil-doers of the same kidney. Another great service rendered to the community by this same body has been the exposure of the wretched system of life insurance of children amongst the poor. It is now some years since Mr. Waugh exposed the horrors of baby-farming, where filth, starvation, and neglect were the indirect but certain means of securing the insurance money. Bad as all these things are, we have by no means come to the end of the list. For instance, there is the question of death certificates, and the facility with which they may be obtained. Nothing is more common than for a medical man to be called in once to a dying child in order that a death certificate may be subsequently obtained from him. The only apparent remedy would be for all medical practitioners to unite and determine not to sign a certificate under such circumstances. Even then it is in the power of the coroner to refuse an inquest and himself grant the necessary certificate, a course to which he is urged by the necessity of keeping down expenses. Such, then, in brief outline, are the chief causes of the excessive death-rate among children generally; but when we come to consider the more particular mortality amongst illegitimate children, we are confronted with the startling and suggestive fact that it is double that of legitimate offspring. On further inquiry into their circumstances it is at once evident that the maternal care will in many cases be necessarily denied to the infant, who will be handed over to strangers. Moreover, the majority of cases of illegitimacy occur amongst the poor, who are unable to contribute a proper sum to the maintenance of the children. Then, as regards the still-born infants, there is no doubt that illegitimacy with its attendant burdens and reproach acts as a powerful incentive to criminal practices. The question of death certificates assumes a doubly important place with regard to the burial of still-born children. At present they are often buried without any certificate at all, or on the strength of a document signed by an ignorant midwife, who may possibly not have been even present at the birth. Indeed, the columns of the Medical Press and Circular have reported from time to time many cases which would more than warrant a searching inquiry into the ways of undertakers, nurses, midwives, and cemetery authorities in the disposal of the bodies of the still-born. Dr. Tatham, late Medical Officer of Health for Manchester, has made some concise statements bearing on this part of the question. In his evidence before the House of Commons Committee on death certification, he made the remarkable assertion that 45 per cent. of still-born infants are annually interred in Manchester without proper notification. So careful an authority is hardly likely to have published these figures without careful consideration; still, the peculiar difficulties attending an investigation of the subject of still-born burials makes us the more anxious to know on what grounds these statistics have been compiled. From whatever standpoint, however, we survey this important question of excessive infant mortality, legitimate and illegitimate, we shall find it impossible to avoid the conclusion that some drastic reform is needed in our present loose system of granting death certificates. It would be unreasonable to hope for any great improvement—any lessening in this nineteenth-century massacre of infants, until it is rendered a penal offence to bury an infant without a medical certificate, which must, moreover, be limited and safeguarded in several important particulars.

◆

Notes on Current Topics.

The Growth of the Shilling Dispensary in Dublin.

A few weeks since we noticed the starting by a new practitioner in a suburb of Dublin, through the agency of a number of female busybodies, of a pseudo-philanthropic dispensary of the "provident" type. The fact of itself is scarcely worthy of notice, inasmuch as speculative doctors and aggressive elderly ladies usually gravitate together, and it does not very much matter what method of operations the co-operation adopts. But from insignificant beginnings results worthy of notice sometimes arise, and the extension of this evil obliges us to speak. Another medical shop has been started in a tenement house close to the Courts of Law, under the name of the "Dublin Medical Mission," where doctoring and piosity are served out together, and we are told that enterprising practitioners have started others in Gloster Street and in Lombard Street. We learn with regret that the number of these sham philanthropic dispensaries is about to be increased by the opening of one more by two Fellows of the Irish College of Surgeons, who have, we suppose, been driven to adopt this most objectionable method of getting business by the touting of the suburban practitioner to whom we have referred. The agents of this latter gentlemen have been busy, as we are informed, circulating prospectuses and personally canvassing patients, even in the families of medical men in his district, and the speculators in the new venture excuse themselves by the plea that to live they must adopt the same tactics. We cannot have any sympathy with this view. A small and early candidate for practice may, if suffering the pinch of hunger, be excused for adopting any means to get a livelihood. As far as we know, all the proprietors of these shilling dispensaries in Dublin are quite above monetary pressure such as might justify their proceedings. Moreover, humble Licentiates and beginners may be excused where Fellows of the College, hospital surgeons, and seniors must be condemned. We warn all speculators in this line of practice that it may involve them in very serious trouble. The General Medical Council has been engaged at its last two meetings in considering whether a connection with these so-called Medical Aid Associations shall be adjudged to be "infamous conduct in a professional respect," and it is quite possible that Colleges may be moved to take action to prevent their Fellows and Licentiates degrading them by the resort to such methods of practice. The suggestion that these shilling dispensaries are in any sense charitable or philanthropic institutions, or the more nauseous pretence that they are for the promotion of religion, may be dismissed without observation. They are nothing more or less than trading medical establishments got up and maintained for the benefit of the doctors who run them.

Fatalities from Alcoholic Excess.

Among the most foolhardy and supremely absurd so-called feats which are attempted by some persons who have nothing better to do, must be included the swallowing, for a wager, of large quantities of alcohol. One such case was recorded last week. A man entered a public-house in Sheffield and undertoook to drink twelve glasses of beer within an hour if anyone would pay for them. A person, who must at the time have been fairly alcoholic himself, actually intimated his willingness to provide the beer, and the "feat" was begun. The beer was brought in a glass at a time, and was, as might be supposed, unhesitatingly consumed. Nine consecutive glasses had thus been emptied of their contents in about half-an-hour, when the proceedings came to a sudden termination. The man became profoundly comatose, and after he had been returned in a cab to his home a medical man was sent for. Before, however, the arrival of the latter, death had taken place. Another fatal case from alcoholic poisoning occurred on Boxing Day, at Birmingham, and in this instance a grocer's assistant suddenly swallowed a pint of rum which had been ordered for the mutual enjoyment of a party of convivial friends. Lastly, a child was poisoned last week with some whisky which it had inadvertently drunk, and despite every effort which was made to avert a fatal result, death nevertheless took place. The deep coma which is associated with the excessive ingestion of alcohol leaves the medical man but little chance of saving life, even when he is summoned to the case soon after the toxic effects have become declared.

Lord Coleridge and Anti-Vivisection.

The Lord Chief Justice of England, it must be confessed, does not do himself credit in the part which he plays in the anti-vivisection movement. His last act has been to write to the Secretary of the Society for Promoting Christian Knowledge, intimating his determination to refuse to pay any more subscriptions to that body. He explains that he has "learned from what seems unquestionable authority that those who administer the affairs of the Society have finally decided to take up their position among those favouring the practice of vivisection and advocating its horrors" (*sic*). Upon these grounds, therefore, Lord Coleridge observes that he feels that it is his duty to withdraw his subscription. Is the dark spirit of the Middle Ages still upon us? Most persons, we imagine, would be inclined to think so after reading the facts to which attention is here drawn. But further comment upon this case would be superfluous. Suffice it, therefore, to say that we heartily congratulate the Society for Promoting Christian Knowledge for refusing to be dictated to by a clique of faddists, and for maintaining their right to issue literature in which, in this particular instance, in their opinion, neither morality has been assailed nor evil doctrines promulgated.

Sickness among Medical Men.

The Medical Sickness, Annuity, and Life Assurance Society, which can fairly claim to be one of the most successful Benefit societies which has ever been founded, contains from time to time in its monthly reports some interesting facts regarding the prevalence of sickness among medical men. At the December meeting of the Committee, for instance, the report shows that a very heavy list of sick claims was presented, owing to the prevalence of the epidemic of influenza, which seems to have fallen with exceptional severity upon medical men. Again, during November last, it is curious to note that the sickness claims of the Society exceeded those in November, 1892, by *seventy per cent.*, and the Committee anticipates that during the present winter the amount of sick benefit received by the members of the society will exceed that paid in any previous winter since the foundation of the Society in 1884! Further, it is interesting to observe that a marked feature of the winter claims is the number arising from accidents in riding and driving. These, for the most part, happen to country practitioners, who are specially exposed to risks of this description in the short dark days of winter. Apart from the great utility of this Society to medical men, one of its most excellent features is that the total management expenses are under five per cent. of the premium income. The customary rate among insurance societies varies from fifteen to thirty per cent.

Poor-law Attendance in Islington.

An incident which is reported from the Islington Workhouse should draw the attention of the Local Government Board to the management of that institution. When the labour-master went round the wards at seven in the morning, one of the aged inmates was apparently sleeping, and was allowed to remain undisturbed. An hour later, however, when an aged female pauper went in to clean the ward, she found the old man was dead, and had been so for some time. The Islington coroner remarked that there should be a night attendant in the old men's dormitory, a recommendation which was also urged by the jury. In these enlightening times it goes without saying that the supervision of the aged and infirm should be systematically carried out by a sufficient staff of able-bodied attendants. Judging from the cases that come to light from time to time, it is not unlikely that a careful investigation into the management of Poor-law institutions in Great Britain would reveal a great number of similar instances of scandalously inadequate attendance.

The Forthcoming International Medical Congress.

We are requested to announce that the Committee has opened in Rome a special office to provide lodgings for Congress members at hotels and private houses. Members can apply also in the same connection to Messrs. Thos. Cook and Son, Piazza Martiri, Rome, who have been requested by the Executive Committee to satisfy such applications when made in time. Excursions will be arranged in Rome under the guidance of Professor Forbes, member of various learned societies. Congress members intending to see Naples and Sicily can travel from Rome to Naples at a 50 per cent. reduction on the usual railway fares, and can join the excursions which will be arranged by the Naples Agency of Messrs. Thos. Cook and Son. This Agency will arrange an undetermined number of excursions to Pompeii, Vesuvius, Capri, Sorrento, Castellamare, and iae, and three to Sicily with the following itinerary: Naples, Messina, Catania, Faormina, Girgenti, Siracusa, Palermo, and Naples. Among the papers to be read at the Congress is one by Professor A. Jacobi, New York, the title of which will be "Non Nocere." The annual meeting of the German Chirurgical Society has been postponed to enable the German surgeons to attend the Congress.

Admissions to Lunatic Asylums.

We reported recently certain law proceedings in Dublin in which the Resident Medical Superintendent of the Richmond Lunatic Asylum was made one of several defendants to a suit for damages for the illegal incarceration of a person supposed to be insane. The Resident Medical Superintendent and the medical attendant on the patient were very properly relieved from all liability, as it was admitted they acted with perfect *bona fides*. We note, however, a statement in the newspapers in connection with that case that the Resident Superintendent "recommended that no person should be admitted to the Asylum unless certified as dangerous," and which recommendation the Board is stated to have approved. We confess that we do not understand this statement, and we conclude that the reporter has made an error. Neither the Resident Medical Superintendent nor the Board of Governors, nor the Inspector, nor the Lord Lieutenant himself, have any authority to limit admission to a county asylum to any particular class of lunatics. The innocent, harmless insane, as well as epileptics, and all other sorts of persons suffering from mental diseases, have an undeniable right to admission if duly and formally certified.

Freshness of Antiseptic Media.

Professor Vignon, of the Lyons Faculty of Science, calls attention to the fact that much of the efficiency of antiseptics is lost by keeping. He has found that lint and cotton-wool impregnated with bichloride of mercury lose their antiseptic power by reason of the combination of organic substances from the air with the salts of mercury, and that solutions of bichloride also deteriorate by keeping. The loss in the latter case after eight days' keeping was 43 per cent.

The Irresponsible Sale of Poisons.

The facts related at an inquest held at Hampstead the other day forcibly illustrated the loose way in which the sale of poisons is regulated in this country. It appears that a housemaid in that locality suddenly made the startling announcement, "I have taken sixpennyworth of poison." She was taken to a hospital and developed symptoms of strychnia poisoning, from the results of which she quickly died. Before her death the unfortunate girl stated that she had obtained the poison at an oilshop, where she asked for "something to kill mice with." Had this poison been obtained from a chemist, he would have rendered himself liable to a heavy penalty. Every sensible man will agree with the jury in their remark that it is full time restrictions should be placed on the sale of poisons in oilshops. This is one of many public health matters that urgently call for attention at the hands of the Legislature.

Hydrophobia in London.

A verdict of death from hydrophobia was returned by a coroner's jury last week in St. John's Wood. The deceased, wife of a local grocer, was attacked by a strange cat, which bit her left hand and scratched her left leg. After an interval of some weeks the wounds appeared to be healing, when the unfortunate woman was attacked with severe pains in the left hand and down the left side, followed by foaming at the mouth and other symptoms of hydrophobia. Fortunately such cases as the foregoing are extremely rare, as hydrophobia does not appear to be very prevalent among cats. The muzzling order, notwithstanding its unpopularity among dog-owners, has practically abolished this terrible disease from protected districts.

Serious Charge against a Parish Doctor.

An inquest was held last week at Bethnal Green upon the body of a child of five. It seems that the parents obtained an order for medical attendance from the relieving officer, and called in the parochial medical officer, who, it was stated by the mother and father, was drunk, and rolled about the room when he visited the house. The child became convulsed, and died soon after taking some medicine sent by the medical officer in question. The latter stoutly denied that he was drunk, and states that the mixture consisted of iron and ammonia. The inquiry has been adjourned in order that an analysis may be made of the stomach and of the remaining portion of the medicine.

"The Grand Old Man" of Medicine.

The "Grand Old Man" of Medicine seems to be Dr. Oliver Wendell Holmes. The College Club of Boston recently gave a reception in his honour, and about 500 persons were presented to him. He received them as he sat "in a laurel-decorated chair under a bower of palms." During the course of the proceedings Dr. Holmes recited "The Last Leaf," "Dorothy Q.," and "The Chambered Nautilus," all of which must have been intently listened to. Truly we have no one in this country, of similar standing belonging to the profession, who could perform such a feat. Fancy Sir Spencer Wells, for example, reciting "The Dream of Eugene Aram" at the *conversazione* of the Medical Society!

An Unusual Sequela in Pleurisy.

A most unusual result of an attack of pleurisy was recorded in a paper read at a recent meeting of the Lyons Medical Society by Lépine. The notes of the case were as follows:—The patient, a man, æt. 59, had taken part in all the wars of the Second Empire; then from 1870 to 1892 he was a cook on board mail steamboats. Despite, however, his active life, he had always enjoyed fairly good health. He had never suffered from any malarial attack, nor from yellow fever, cholera, nor dysentery, neither had he had syphilis or lead poisoning. The only illnesses from which he had suffered were four attacks of acute rheumatism: the third of these attacks was complicated with left pleurisy, the fourth with endo- and pericarditis. After recovery from the latter illness examination of the left side of his chest showed that there was marked flattening, the exact measurement being four centimetres and a half less on the left side than on the right. All the muscles of the shoulder were atrophied, the deltoid more so than any other. Without being manifestly atrophied, the whole of the limb showed great weakness, as was indicated by the dynometer, the power being less than half that displayed by the right arm. In addition to these symptoms there was general anæsthesia, together with the loss of heat-sensation over the left chest and the corresponding shoulder and arm. Pain was absent everywhere, and it was not possible to produce any painful sensation in the affected areas; the reflexes were normal. The author drew attention to the extreme rarity of such a case, although two cases somewhat similar had come under his notice in 1873. The most difficult feature in the history of a case of this kind was the precise pathological condition upon which the symptoms depended.

Unqualified Medical Missionaries.

"Dr. Harford Battersby, formerly a medical missionary in the British Dependencies along the river Niger, has become the principal of a new medical school in London." This is the opening paragraph of a leading article headed "The David Livingstone Medical College in London," which appeared in a recent issue of an American contemporary. The announcement is quite news to us. So far we have been unaware of this enterprise of which our contemporary speaks so favourably. But there can be no question that in more ways than one quasi-colleges established for the medical training of missionaries would be calculated to do more harm than good. The smattering of knowledge which a missionary trained under such auspices would be likely to get would make him a dangerous exponent of medical science even among the poor natives among whom he had cast his lot. A duly qualified, competent medical man or woman should be attached to each mission station, or, failing this, the medical treatment of the natives should not be undertaken. It is well known that the practice of modern medicine and surgery has a marked influence in advancing the cause of civilisation among the pristine inhabitants of the countries in which missionaries labour. If, then, a missionary has neither the time nor the funds to qualify himself for medical practice in the ordinary way, it is only expedient that he should not attempt to assume the responsibilities of a medical man.

We notice but one recipient in the profession of New Year honours in the official list, that of Surgeon-Major Ernest Harold Fenn, who is gazetted a Companion of the Indian Empire.

The Death of Dr. Guttmann.

ONE of the victims of the prevailing epidemic at Berlin, last week, was Dr. Guttmann, the well-known editor of the *Deutsche Medicinische Wochenschrift*. In fulfilling the calling of a medical journalist he obtained a wide reputation, and his death has undeniably created a loss in the profession which will not be so easily filled up. The immediate cause of death was cardiac syncope occurring in the course of a severe attack of influenza of ten days' duration.

The Post of Medical Officer of Health for Manchester.

THE post of Medical Officer of Health for Manchester, recently vacated by Dr. Tatham, is still unfilled, and nothing will be definitely decided about the matter until after the meeting of the Manchester City Council next week. Meanwhile a Committee of the Council has drawn up a special report respecting the duties and emoluments of the appointment, and it is recommended that the salary should be £850 per annum. There appears to be, however, a feeling in some quarters that this latter recommendation will be subjected to a good deal of criticism in the Council, on the grounds that the sum offered is excessive. In the true spirit of economy, also, an alderman has suggested that the offices of Medical Officer of Health and City Analyst should be amalgamated, with a view to the saving of expense. It may be hoped that no cheese-paring policy will be allowed to influence the settlement of the details in connection with this important appointment. The Medical Officership of Health for Manchester is one of the most responsible in the Kingdom, and the Manchester City Council would be committing a serious error of judgment were they to do anything at the present juncture which would have the effect of diverting well-tried and thoroughly competent candidates from competing for the post.

Another Isolation Hospital Difficulty.

THE inhabitants of Kingston are the latest to be up in arms against the proposal to establish a hospital for infectious diseases in their midst. The name of the proposed site is Fern Hill, which is situated about half a mile from the barracks at Kingston. Apparently the Corporation of Richmond is answerable for the opposition which has been excited. An agreement was recently arrived at by this body to the effect that an isolation hospital was required for the district, and the fact was at the same time pointed out that there was no available site for the erection of such an institution within the borough boundaries. While, however, inquiries were being made in respect to a suitable locality for the hospital, an undertaking was given by the Corporation not to invade either the districts of Petersham or Mortlake. This, then, is the grievance of which the inhabitants of Kingston complain. They protest that they have never been consulted in the matter, and still, despite the fact, and irrespective of other available sites, a hospital for infectious diseases is proposed to be erected in their midst. The Local Government Board has been appealed to with the view to setting aside the pledges given by the Richmond Corporation to the district authorities of Petersham and Mortlake. It is held that these pledges cannot be advanced as reasons for one district going outside its own area for the purpose of planting "objectionable things" upon that of its neighbours. It remains to be seen, however, what action the Local Government Board will take in the matter. Meanwhile, it seems hardly fair to the Kingston residents that their district should have been fixed upon, while the two other districts above mentioned have been allowed, so to speak, to go free. Obviously the settlement of this question should entirely depend upon the site which is admitted to be the most suitable for the purpose, quite irrespective of the district.

A REUTER'S telegram from Calcutta reports that Surgeon-Captain Pearce has been called upon to show cause why a further charge should not be made into a charge of culpable homicide. It will be remembered that this officer was lately tried and acquitted of a charge of having shot a native without provocation. It is announced that the forthcoming investigation will be open to the public.

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

THE PAST YEAR IN EDINBURGH.—Last year has been uneventful with regard to medical doings. The most notable thing which occurred was the commencement by the University of the new rules adopted by the Commissioners with regard to the enrolling of students and taking of fees. At the beginning of the year grave doubts were expressed whether the number of students was not falling seriously owing to the adoption of the five years' curriculum. This winter, however, in the University, at any rate, the numbers are much the same as formerly, the figures being as follows:—Total, 1,278: of these 243 are in the first year of study, 220 in the second, 233 in the third, 271 in the fourth, and 311 in the fifth year. The large number in the last year is due to the fact that all chronics are charitably placed in it. The hospitals in Edinburgh continued to enlarge their respective spheres of usefulness. The Infirmary opened its gates to lady students and provided accommodation for them. A general appeal to the public for the purpose of raising funds for an extensive enlargement of the Hospital was postponed owing to the widespread loss caused by the failure of the Australian Banks. The close of the year finds the Infirmary Board face to face with the question, Should the acting staff be directly represented on it? The College of Surgeons has elected two of the surgical staff to the vacancies on the Board. In the ordinary course of events they will take their seats this week. It is understood that there is a strong feeling of opposition to their doing so. The new Sick Children's Hospital is gradually assuming shape and form on the opposite side of the Meadows to which it formerly stood. The new East House at Morningside Asylum is nearing completion. During the year several epidemics occurred.

At the beginning of the year measles was extraordinarily prevalent, while small-pox broke out in Leith in spring and again during the winter, and influenza made its annual appearance in late autumn in a severe form. The only medical conference held in the city was that of Public Health in July last.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

LARYNGOLOGISTS AT THE PATHOLOGICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In offering you my cordial thanks for the able and unbiassed statement of the case as between Dr. Semon and myself, which appears in the current number of the Medical Press and Circular, I ask you to evince still further your well known love of fair play by according me yet a small space in your columns.

I pass over by mere reference the facts that:—

(1) It was not "a year or two" but two years and seven months, and after issue of three volumes of Transactions, that elapsed since Dr. Semon first exhibited at the Pathological Society this "anomalous tumour," for which the word "colourless" can hardly be considered a synonym.

(2) The circumstance that the substitution by me of the word "occasional" for "frequent" degeneration of benign into malignant growths was not made for the first time the other night, but may be found since 1887 in all the later editions of my book, and that an even less uncompromising position is taken in my essay in the Anglo-American work to which Dr. Semon took exception.

You, Sir, rightly contend that "malignancy remains more a clinical than a pathological phenomenon," and herein lies the crux of the case. In May, 1891, neither "the situation of the tumour" nor the "occurrence of spontaneous hæmorrhage" afforded Dr. Semon any "evidence of malignancy," but when the fatal result occurred and the case was decided to be without doubt malignant from the first, these symptoms coupled with two others not previously noted, namely, dysphagia and alcoholism, were emphasised as signs which should have been all along interpreted as of evil omen. Why were they not?

In what degree then have I not treated Dr. Semon with fairness, save that I accepted without question the accuracy of his diagnosis as a clinician and that of Mr. Shattock as an histologist? for the second opinion which I am accused of suppressing that the growth was malignant from the first, is inconsistent with his statement in his first report that neither clinically nor pathologically was there "evidence of malignancy."

To one mistake I do acknowledge, in that instead of claiming Dr. Semon as a "more or less willing *adherent*" to my views, I should have referred to him as a more or less willing *witness*. Had I used the latter word there would have been no justification for Dr. Semon's wrath, but on the other hand the Transactions of the Pathological Society, so far as this case is concerned, would, by being deprived of the full sequel, have remained incomplete and misleading.

I am, Sir, yours, &c.,
Lennox Browne.

15 Mansfield Street, W.,
28th December, 1893.

DIPHTHERIA, HOW IT ORIGINATES AND HOW IT SPREADS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As a good deal of discussion is going on at the present time upon the subject of diphtheria, the few following thoughts may possibly prove helpful.

The first question that arises is: *What is the origin of diphtheria?* and I think there can only be one answer, viz., defective sanitation of some kind or other—the same as it is of all other infectious disease.

In the second place we have to ask ourselves the question: *By what means does it spread?* Well, it increases (*a*) by contact of an individual suffering from the disease with others; (*b*) by direct contact of an infected individual or special germ conveyed by an intermediate person, say by means of the hands or clothes, with milk or water; (*c*) by contamination of milk or water through the medium of sewer gas.

Besides these things there are various others which greatly assist in its propagation:—

1. The daily constant communication of children in the Board schools.
2. The ignorance of medical men as to what forms of sore-throat are infectious and what not.
3. The dark and damp condition of many dwellings, which tends to keep the germs alive and favour their development.

It has of late been shown that diphtheria is now more prevalent in the towns than in the country districts, and the question is asked, how has this come about? Well, in the old days, when cesspools were the order of the day, it was more common in the rural districts, owing to the fact that there was worse sanitation in these than in towns—but in course of time, when the early system of drainage was introduced into the cities and communication with the rural districts became more easy, then it was more frequently introduced, and through the supposed sanitary improvements widely spread. Board schools have also, as I said before, greatly helped to accentuate the increase of the disease, and will continue to do so till we get more regular systematic sanitary inspection. Notification, I venture to say, by itself will prove, more or less, a failure in reducing the death-rate, as it has done up to the present time.

I am, Sir, yours, &c.,
F. P. Atkinson.

Surbiton.

ANÆSTHETICS IN OPERATIONS ON THE THROAT AND NOSE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the last fortnight two more deaths have occurred from the administration of chloroform during the removal of adenoid growths from the naso-pharynx. In one case I have reason to know that the danger of this anæsthetic was pointed out, and the alternative employment of nitrous oxide gas forcibly, though unavailingly, urged.

Letters have been recently printed in the columns of the Medical Press and Circular, and in those of its two weekly contemporaries, from the pens of Mr. Lennox Browne, Dr. Dundas Grant, and Dr. Wyatt Wingrave respectively, urging the complete safety and efficiency of nitrous oxide gas in these operations. All of these gentlemen are attached to the Central London Throat and Ear Hospital, where this gas has been employed during the last three years on about 2,000 occasions with complete efficiency and without accident. I have myself been responsible for the administrations in nearly half this number, as well as in two to three hundred other cases in private practice.

The now long list of fatal results from chloroform is calculated to bring a valuable operation into disrepute, and I venture to say with all respect, that in the light of the foregoing experience, the word "misadventure" cannot much longer be properly applied to the verdict.

I am, Sir, yours, &c.,
W. G. Holloway, M.B. Camb.,
Registrar and Anæsthetist to the Central London Throat and Ear Hospital.

January 1st, 1894.

◆

THE PROPOSED NEW ORDER OF MIDWIFERY PRACTITIONERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The action of those medical practitioners who now grant Midwifery Diplomas to women, and which em-power the holders to *practice Midwifery*. has stimulated others, to examine, and grant a *diploma in medicine*. No doubt there will soon be a third body, which will examine and grant a *diploma in surgery*, so that all the bone setters, unqualified assistants, and prescribing dentists, may be granted a diploma. When this comes about there will be a complete repeal of the Medical Act of 1886.

Lately, "The Magnetic School of Medicine, Limited," and "The General Council of Safe Medicine, Limited," have been established. They have been registered as Limited Liability Companies, under the Board of Trade, not having a capital divided into shares. Registration was effected on March 15th, 1893.

The following is the Memorandum of this new diploma-granting Body:—

"Memorandum of Association of the General Council of Safe Medicine, Limited.

1.—"The name of the Company is:—"The General Council of Safe Medicine, Limited."

2.—"The Registered Office of the Company shall be situated in England.

3.—"The objects for which the Company is established are to grant Degrees, Scholarships, Awards of Merit in the Magnetic and Botanic System of Safe Medicines, to students passing a satisfactory examination before the General Council of Safe Medicine, and to those of the Botanic Profession of good moral character, and who can produce a reliable evidence of qualification, or ten years' practice, at the discretion of the Council. The highest diploma of the Council conferring the distinction of M.D. (B.C.), which shall signify the rank of "Doctor of Botanic Medicine," in contradistinction to surgery, and the practises of the Allopathic, and Homœopathic Schools of Medicine, also to maintain a Lecture Hall, Library, and Record Office, in which a biographical record of its members shall be kept as far as obtainable.

4.—"Every member of the Company undertakes to contribute to the assets of the Company in the event of the same being wound up during the time that he is a member, or within one year afterwards, for the payment of the debts and liabilities of the Company contracted before the time at which he ceases to be a member, and the costs, charges, and expenses of winding up the same, and for the adjustment of the rights of the contributors amongst themselves, such amount as may be required not exceeding £5.

"We, the several persons whose names, addresses, and descriptions are subscribed, are desirous of being formed into a Company in pursuance of this memorandum of association."

V. Trimming, Clerk in Holy Orders, five medical herbalists, and one merchant sign this memorandum.

The General Medical Council have had their attention called to this proposed now order of medical practitioners, and I have called their attention to the action of those medical practitioners who are now selling midwifery diplomas to women.

These have set a fatal example, and it is not to be wondered at that others are now following their lead. If we practitioners sell diplomas in midwifery we shall soon have a shoal of herbalists, bonesetters, and others with their M.D. diplomas. Is it too late to entreat these medical practitioners to cease their down-grade and degrading work? It will be a long time before barristers, solicitors, veterinary surgeons, or chemists prostitute their several callings by creating a low order of their faculties. I would, therefore, ask those practitioners who are now trying to establish a new order of midwifery practitioners to cease granting diplomas. The qualifying bodies under the Medical Acts should alone grant medical diplomas. But with the present sad example how can we blame "medical herbalists" for following in the footsteps of those who are striving to repeal the Medical Act, which enacts that no one should practise medicine until he has studied for five years, and taken a registrable qualification in medicine, surgery, and midwifery?

I am, Sir, yours, &c., Robert Rentoul.

◆

We regret to announce the melancholy death of Dr. Milnes Marshall, F.R.S., the eminent Professor of Comparative Anatomy, in Owens College, Manchester, on Sunday last. Deceased had climbed the Scawfell, when he missed his footing, fell over a precipice, and was killed instantaneously.

Literature.

MACEWEN'S ATLAS OF HEAD SECTIONS. (a)

Now that brain surgery has become so important an offshoot of surgical practice, it was inevitable that plates dealing with and illustrating the sectional anatomy of the brain, and the surgical topography of the scalp and cranium should require publication. Already some very good work in this direction has been done, notably by Professor Fraser of the Royal University of Ireland; but it is not surprising—it was indeed very desirable—that a man of Dr. Macewen's eminence in this department of surgery should, from the surgeon's point of view, and with the surgeon's practical experience, undertake the investigation of the matter, and the publication of his results. A work of this kind, in order to be thorough and worthy of reference, necessitates the examination of a multitude of specimens, and very careful discrimination in the selection of sections. The Atlas has been prepared from frozen head sections, fifty-three in all, and key sketches have been drawn from the original. At any spot which may be selected for operation, the relations of the various parts of the brain to the outside of the skull may be seen in three different series of sections—coronal, sagittal, and horizontal. A still further point of importance is that child and adult sections may be compared in the coronal and horizontal series, and the difference in the size of the brain relatively to the rest of the head is in these sections very noticeable. Among several practical suggestions made by Dr. Macewen may be noted the following:—(1) the proximity of the nasal recesses to the intra-cranial structures suggests an easy access for erosive infective processes; (2) for eradication of infective matter extending from the nasal fossæ through the cribriform plate of the ethmoid, or by way of the frontal sinuses, trephining in the middle line of the brow at the glabella, and penetrating the frontal sinuses, affords the best means of exposing the seat of disease. Other practical points are the liability to pressure on the third nerve from the basal portion of the tempero-sphenoidal lobe, and the shape of the cerebellum as seen in these sections compared with its appearance when removed from the skull. These observations are made by the way, and are but a drop in the bucket of what may be gleaned by a careful study of this volume and its exhaustive illustrations. The coronal sections are in three series—males at 60, 40, and 2½ years. The sagittal sections are in one series—male, æt. 30; and the horizontal are in three series—male, æt. 35, 50, and 5 years. The fact that there is no comparison of male and female sections may not appear worth consideration, but anatomically it makes the Atlas incomplete. As a guide to operations more detail as to the precise surface topography of the sections would have been a decided gain. The work is excellent, extremely valuable so far as it goes, but it requires a supplementary treatise to aid men adventuring in the region of brain surgery.

MACEWEN'S BRAIN AND SPINAL CORD. (b)

This is a work which will readily be appreciated by the general medical public, as well as by aural and brain surgeons. Dr. Macewen's work for many years has lain in this region of surgery, and such a careful antiseptic surgeon as he is known to be must necessarily have had his thoughts much occupied with the study of infective pyogenesis. A perusal of this book will satisfy the reader that the whole subject has been surveyed with an all-round conception of its difficulties and manifold intricacies. Believing that the temporal bone is the *fons et origo* of much of the abscess formation within the skull, he devotes considerable and elaborate attention to the anatomy of this bone and the structures running through it, and while giving all necessary attention to the ear mechanism, he emphasises the fact that the squamous portion and the mastoid cells are even more important. Not less particular is his description of the structure and channels of communication of the cerebral membranes, and the water cushions of the base studied as channels of septic infection. The chapter on pathology is equally full and instructive; but the grit of the work is really in the clinical chapters, which are replete with interesting cases, and remarkable results told in a clear crisp style that makes these records all the more likely to be carefully read, and all the more valuable. This work of Dr. Macewen's is worthy of himself and his eminent position in the domain of cerebral surgery.

IRELAND'S BLOT UPON THE BRAIN. (a)

WE have had occasion to review most favourably the first edition of this excellent and original treatise, and it was with unfeigned satisfaction that we observed the appearance of a second edition. One merit of it from the author's and publisher's point of view is the fact that it is a treatise as free from medical technicalities as a work of this kind can possibly be, and this makes it commendable to a much wider circle of readers than would otherwise be possible. To the student of history it is an extremely readable and suggestive book, and the study of morbid psychology as the key to much that in history is puzzling and obscure will be found, and doubtless has in some measure already been found a most profitable and exciting occupation. The new edition shows that Dr. Ireland with open mind is ready to note the criticisms of his work, and as far as possible to profit by them. It might seem unnecessary in a work so essentially historical to revise and rewrite for a second edition; but Dr. Ireland is nothing if not thorough, and in his endeavour to keep the work abreast of scientific research he spares no pains. History is one thing, the true psychological explanation of it by the light of modern research is another thing, and being a true student of history, this Dr. Ireland very well knows. We heartily commend this new edition.

STARR'S BRAIN SURGERY. (b)

THIS is a work of clinical interest which, from the point of observation and experience of the neurologist and psychologist, is amply stored with information in illustration of the various morbid conditions amenable to surgical treatment. It is a work which represents the condition of things which calls for the interference of the surgeon, and which also enables the practitioner to make his own preliminary diagnosis and know his ground. As the author well observes, there are two essential preliminaries to any operation upon the brain; the first is the diagnosis of the nature of disease which is present, and the second is the diagnosis of its situation. Both are purely medical questions, and this is the text of the book, which is not so much a book for the surgeon as for the physician and general practitioner. The first chapter deals with the diagnosis of cerebral disease, specially considering such diseases, and such sites as come within the reach of the surgeon's instruments. The salient points of localisation and their outward signs are described, and cranio-cerebral topography is succinctly delineated. The conditions considered as most frequently requiring operation are epilepsy, microcephalic imbecility (?), cerebral hæmorrhage, abscess of brain, tumour, hydrocephalus, and insanity. The work is well illustrated, the get-up of the book is excellent, and though not exhaustive—it does not pretend to be—it is a work that will repay perusal, and be found useful as a ready and concise guide to the study of diagnosis in preparation for cerebral surgery.

WALLER'S HUMAN PHYSIOLOGY. (c)

A PERUSAL of the second edition of this work deepens the impression made by the first. Dr. Waller calls the book an "Introduction," for most people, and for the ordinary requirements of the average student or practitioner, we should say that everything necessary is to be found within its boards, leaving out of account some physiological chemistry. The whole volume is instinct with the thorough grasp which the author has over all physiological problems, is pleasant to read, but yet scientifically expressed, and is not so aggravatingly up to date as it might be. This last qualification is not uncalled for. No subject is so easily spoiled by overloading as physiology. The division of the book which seems most capably and fully worked out is that which deals with nerve and muscle, their electrical reactions, and indeed the whole subject of animal electricity. Those puzzling questions for beginners, the nature of anelectrotonus and katelectrotonos, the diphasic variation during the contraction of the ventricles of the heart, and the differences of excitability in nerves and muscle depending on anodal and kathodal stimulation are very clearly illustrated and explained. The account of digestion is not quite so lucidly stated, and may well cause some little confusion on reading. A word should be added in praise of the very numerous illustrations scattered throughout the volume.

STURGES' CHOREA. (a)

THE principal purpose of the work before us is to show, as the author states in his preface, that chorea is in large measure a disease of function, due to preventible causes, and that guidance is not wanting as to the sort of training and management which affords the best security against its attacks and the surest means of its cure. In his introduction he discusses the place in Nature of functional nervous disease, and makes the remark, with which many will not agree, that the observation of disease in its functional relations, if less complete than the organic, has greater security, for the facts appealed to are exhibited in their life and working without undergoing in the analysis that process of dissection which implies death and may involve mutilation.

Of his chapter on the general description of the disease little need be said, as it introduces practically nothing new of interest. In it he objects to all definitions of the complaint previously given, and says that to ordinary observation, at all events, chorea consists in an "exaggerated fidgetiness," a definition which, we think, is certainly no better than its predecessors.

After discussing its relation to rheumatism he appends, as his conclusions, the remarks that the number of instances where rheumatism is *immediately* connected with chorea is very small, and that in the majority of cases of chorea occurring in children supposed to have been rheumatic, the immediate exciting cause of the chorea is no other than that which suffices to produce the same affection in other children who are not rheumatic. He allows, however, that in rare instances acute rheumatism appears as a cause of fatal chorea.

With regard to heart complications, he states that they are more marked in early than late childhood, and that papilliform endocarditis affecting the mitral valve, a condition which is rarely seen in any other associations, is the cardinal anatomical feature in chorea, wholly apart from rheumatic endocarditis.

He next briefly discusses the various hypotheses as to the pathology of chorea in chronological order, and comes to the conclusion that morbid anatomy fails to account for the disease, and that, although the affection is chiefly of the nature of a functional disturbance, the association with rheumatism and endocarditis renders a purely functional hypothesis insufficient, and that there are reasons for regarding chorea as of the same pathogenesis as acute rheumatism, virtually distinct as diseases, though owning a common origin.

As regards the treatment of the disorder, the author relies practically altogether on moral measures, and considers that chorea should be exempted from the number of disorders that drugs can cure.

He furnishes illustrative cases in the last chapter as support for his views on the pathology and treatment.

On the whole the book does not add much to our knowledge of chorea either from a practical or theoretical standpoint.

METCHNIKOFF'S COMPARATIVE PATHOLOGY OF INFLAMMATION (*a*).

THE translators of this work have conferred a great benefit on those of the profession in England who happen not to be conversant with the French tongue, for a more interesting and suggestive book it has rarely been our lot to read. Beginning at the very lowest forms of animal life, the author has endeavoured, and that with what appears to us to be perfect success, to place before his readers the evidence afforded by those rarely organisms of the nature of the struggle between their protoplasm and their foes. In the first place he proves conclusively that as phenomena of inflammation occur in organisms which have no circulatory system, phenomena very similar to those occurring in higher life, the essential part of the process cannot depend on the blood or its vessels. A description of positive and negative trophomorphism, or as it is now better known as, chemiotaxis, follows. Protoplasm in the living state is attracted by some substances, repelled by others, it hastens to engulf and destroy some micro-organisms, it flies from others. Leucocytes, especially the large polynuclear corpuscles, possess the same properties. The introduction of a poison into the body of a mammal results in some cases, if the substance is positively chemiotactic to the leucocytes, in a struggle *à l'outrance* with varying results; if the poison be organised and negatively chemiotactic the leucocytes fail to engage the enemy, and death results from the unchecked multiplication of the invading host. Throughout the volume the various facts are presented in a most attractive form and with copious illustrations. Whatever may be the ultimate fate of the phagocyte theory of the inflammatory process, the work herein detailed must always stand as an honest endeavour to solve by laborious and painstaking methods one of the most important problems that medical men have to deal with. The translation leaves nothing to be desired, and we confidently recommend a careful perusal of the book to all interested in the subject—and who in medicine is not?—assured that such perusal will open up new and wide fields of thought.

YEAR-BOOK OF PHARMACY. (*b*)

THE past year in pharmacy has been principally devoted to new investigations and a further prosecution of researches already in progress. Messrs. Dunstan, Harrison, Carr, and Jowett have contributed valuable papers on the aconite alkaloids; and at last we know that a definite crystallisable aconitine of reliable physiological action is obtainable.

The uncertainty and doubts that are so long associated with solanaceous alkaloids still continue, and many and prolonged investigations on the subject are still desirable. A good *résumé* of these papers appears in this "Year-Book of Pharmacy," together with a great deal of other interesting matter, including a good account of Auschütz's method for purifying chloroform; and Beringer's criticism on Ehrlich's method of urine-testing as a diagnostic aid to the recognition of enteric fever.

The price of the "Year-Book" places it within the reach of all, and we think that to all whose ambition is success it is a necessity. It is useful, reliable, and excellent summary of pharmaceutical progress in Great Britain.

WADE'S GOUT. (*c*)

DR. WADE bases his proposition on the pain which can be elicited by pressure on the nerves leading to the inflamed parts in gout, and on the relief afforded by massage of these nerves. He also attributes the frequency with which the great toe is attacked to pressure on the comparatively unprotected nerves by the weight of the body. The cause of the neuritis is the state of the blood. It is unfortunate that Dr. Wade does not differentiate between neuritis and peri-neuritis, the latter of which we imagine to be much the more likely of the two to occur under the circumstances, and which would coincide more nearly with his "neuro-humoral" theory. An acute neuritis appears to us to be too serious a condition to be cured so quickly as in some of the author's cases. We have also seen cases in which rubbing of the nerve above the seat of pain relieved it greatly. This relief is more consonant with the presence of a slight peri-neuritis.

SCOTT'S MANUAL OF URINE TESTING. (*a*)

THE present edition contains more matter than the first, and the fallacies connected with the various tests are more clearly pointed out. In addition to tests, &c., there is some information as to the clinical importance of the results arrived at, and there are a good many illustrations of apparatus. The information given seems to be accurate, though extreme condensation sometimes mars its clearness.

◆

Medical News.

Suicide from Chloroform.

DR. GEORGE DANFORD THOMAS held an inquest on the 30th ult., at the Paddington Coroner's Court respecting the death of Sarah Ellen Strange, aged 30, a dressmaker, lately residing at 50 North Street, Edgware Road, who committed suicide by poisoning herself. Mrs. Jane Cole, living at Queen Street, Edgware Road, stated that she had known Miss Strange for eight years. Her parents resided in Ireland, and of late she had been on a visit there. On Saturday evening, on her return home at 10 o'clock, witness was called to the back yard, and found her friend there in an insensible condition. Dr. P. John Head stated that on Saturday night he was called to see Miss Strange, and found her insensible, suffering from the effects of a narcotic poison. He did everything possible, and the next morning he had her removed to St. Mary's Hospital. He saw two bottles containing chloroform, which had been found in the woman's pocket, and also a bottle that had contained laudanum. The Jury returned a verdict of suicide while of unsound mind.

Foreign Vivisectors.

A MEMORIAL has been presented to the Home Secretary by the Victoria Street Anti-Vivisection Society, signed by 15,727 persons, requesting the Home Secretary to withhold licences for vivisection from applicants of foreign birth or extraction. The memorialists state that it is the prevailing opinion that foreign vivisectors are less humane than Englishmen, and that being so they note with alarm that in the inspector's annual reports a considerable number of names of licencees obviously not English. The Home Secretary is scarcely likely to accede to such an application.

Lead-poisoning among Women in London.

MR. CARTER, last week, held an inquest at St. Paul's, Deptford, Vestry offices, respecting the death of Johanna Wood, æt. 22. Mrs. Wood said that for five years on and off her daughter had worked at the Millwall White Lead Works (late Pontifex and Wood). About six weeks ago she became ill and was laid up until her death on Wednesday last. She had had bad fits, and witness attributed the death to working at the white lead. Norah Shea, also employed at the works, said that two years ago she was away from the works in consequence of pains in the head and the stomach. The women were required to wear a respirator whilst working, and to take acid water three times a day. They had also to wash before meals and have a bath once a week. Those regulations were enforced. Mr. H. E. Taylor, the manager of the works, said they employed on an average 45 female hands. They

enforced very stringent regulations. The works were visited by a factory inspector. No woman under 18 was allowed to work there. They engaged a doctor on each side of the river. He did not know that there were several women in Greenwich Infirmary suffering from the effects of working with the lead at his works. The coroner read a list of seven women, whose ages ranged from 17 to 33, who had been in the infirmary since October. Dr. Hartt, of Greenwich, said he was engaged by the firm to attend persons in their employment. He saw the deceased on December 2nd, and found her suffering from lead colic, vomiting and headache. she had a blue line on both upper and lower gums, a sign of lead-poisoning, her muscles were flabby, and her skin very white. She died on December 27th. A post-mortem examination showed that the cause of death was an epileptic form of convulsions, followed by coma, but the exciting cause of death was lead poisoning. Mr. Vaughan, factory inspector for East London, said he visited the works once, but did not make an exhaustive inspection. He had been there that day and found them closed. No doubt female labour should be abolished in such works. The jury returned a verdict "That the deceased died from epileptic convulsions from working in a white lead factory."

Fever Hospital on Hounslow Heath.

Just as we go to press we learn that the Richmond Town Council have definitely abandoned the proposal to apply for a Provisional Order to acquire land compulsorily at Fern Hill, Ham, for the purposes of an isolation hospital. A suggestion for joining with the Heston and Isleworth Local Board has now been unanimously adopted by the council. It is proposed to erect a joint hospital for infectious cases on Hounslow Heath, and thus a conflict with the Kingston Town Council, the Ham Local Board, and the Dysart Trustees, all of which bodies had given notice of opposition to the Fern Hill scheme, has been avoided.

Christmas Fare in an Infirmary for Horses.

There exists at Acton an institution named "The Home of Rest for Horses," and on Christmas Day, through the liberality of a subscriber, all the animals were treated to a Christmas dinner. This naturally did not consist of roast beef and plum pudding, but doubtless the fare was fully appreciated by the animals. There were luscious carrots, apples, and sugar, a most considerate combination.

The Effects of Agricultural Depression.

Another proof of the agricultural depression was afforded in the petition adopted at the Gainsborough Board of Guardians meeting last week against the suggested increase of the salary of Dr. Marsh, as Medical Superintendent at the County Lunatic Asylum, from £400 to £500, in addition to £200 or £300 for house and household expenses. There was a strong feeling against the proposal, as the late Medical Superintendent was receiving a pension of £500 a year. All the Lincolnshire Boards of Guardians were invited to petition against the proposal. The opposition was, of course, in consequence of the unwillingness to pay more rates than was absolutely necessary.

A Girl Poisoned by Rum.

A Coroner's jury at St. Helens last week returned a verdict of misadventure after inquiry into the death of Esther Taylor, aged five, who died on Christmas morning from drinking rum. Her guardian had left a bottle of rum in the corner of the bedroom, and during her temporary absence the child got the bottle and drank a wine glassful, with the result that she became drunk, and convulsions and death supervened.

Death of a Centenarian.

There has just died in the Newbery Workhouse, an inmate named John Shaw, who had attained the age of 103 years. The deceased was a native of Melksham, and a bargeman by trade. In 1847 he lost his wife through an accident, and nearly thirty years ago his daughter was murdered by a butcher in Newbery, the murderer afterwards committing suicide by drowning himself. Shaw had been an inmate in the workhouse for twenty years.

Snapdragon at Guildford.

An alarming incident occurred late on Christmas night at the Royal Surrey Hospital, unfortunately attended with serious consequences. At the time mentioned a number of patients and visitors were amusing themselves in time-honoured fashion around a snapdragon, when one of the house-surgeons present incautiously threw a fresh supply of spirits upon the dish. This latter proceeding led to an outburst of flames which burnt some of the bystanders and ignited the clothes of others. Fortunately, the flames were promptly extinguished by means of blankets. The patients appear to have escaped serious injury, but a clergyman and two choir-boys were seriously hurt. Of the latter, we regret to say, one has since died in the hospital, necessitating an inquest, which has been adjourned pending the fate of the other unfortunate victim.

Vital Statistics.

The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 24·7 per 1,000 of their aggregate population, which is estimated at 10,327,846 persons in the middle of this year, and were—Birkenhead 23, Birmingham 26, Blackburn 13, Bolton 24, Bradford 18, Brighton 19, Bristol 33, Burnley 27, Cardiff 19, Croydon 23, Derby 19, Dublin 30, Edinburgh 20, Gateshead 14, Glasgow 22, Halifax 22, Huddersfield 26, Hull 24, Leeds 17, Leicester 22, Liverpool 31, London 26, Manchester 22, Newcastle-on-Tyne 19, Norwich 18, Nottingham 24; Oldham 16, Plymouth 41, Portsmouth 24, Preston 19, Salford 24, Sheffield 23, Sunderland 22, Swansea 26, West Ham 19, Wolverhampton 35. The highest annual death-rates were—From measles, 1·3 in Salford and 1·5 in Norwich; from scarlet fever, 1·2 in in Wolverhampton and 1·6 in Huddersfield; from whooping-cough, 1·1 in Cardiff, 1·2 in Sheffield, 1·5 in Birkenhead, 2·2 in Bolton; and 4·2 in Plymouth; and from fever, 2·2 in Swansea and 3·5 in Sunderland. The 88 deaths from diphtheria included 63 in London, 4 in Bristol, 3 each in Edinburgh, Glasgow, Birmingham, and Liverpool, and 2 in Gateshead. Four deaths from small-pox were registered in Birmingham, 2 in West Ham, one in London, and one in Liverpool, but not one in any other of the large towns.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 33, Bombay 23, Madras 44, Paris 20, Brussels 17, Amsterdam 16, Rotterdam 27, The Hague 21, Copenhagen 22, Stockholm 21, Christiania 24, St. Petersburg 23, Moscow 31, Berlin —, Hamburg 26, Dresden 17, Breslau 30, Munich 29, Vienna 32, Prague 30, Buda-Pesth 28, Trieste 26, Rome 22, Turin 14, Venice 21, Cairo 46, Alexandria 39, New York 20, Brooklyn 16, Philadelphia 18, New Orleans 25.

L. D. S.—Our columns would not seem to be a suitable medium for your contribution. It would be more likely to attract attention in a dental contemporary.

ANECDOTE OF THE LATE SIR JAMES SIMPSON.

In illustration of her late distinguished father Sir James Simpson's quickness of resource, Miss Simpson relates, in "The Century Magazine," on the authority of a friend, the following ancedote. One day a patient of his was under chloroform, when, owing to a kettle having been upset, the supply ran short. In order to save life, it was necessary to have more without a moment's delay. Those around were in despair, but the illustrious physician instantly cut out the saturated square of carpet, and by its help contrived to keep his patient under the influence of the anæsthetic.

Dr. G. A.—If a newly-arrived practitioner deliberately chooses to neglect the usual socio-professional civilities he must take the consequences. At the same time it would perhaps be better to ascribe his behaviour to a want of *savoir faire* in the absence of any distinct evidence of boorishness.

"POOR CHICKENS."

The following delicious communication appeared last week:—

Russian Influenza.

TO THE EDITOR OF THE ECHO.

Sir,—There is one source of infection from Russian influenza which, as far as I have read, has not been suspected. We must all be aware that nearly every Russian town, village, and hamlet suffers more or less from the worst forms of typhoid, yet we import millions of Russian eggs. Chickens are not particular in their feeding, especially where grain is scarce. Is it not probable that the germs of the above disease may pass through the digestive system of a fowl and appear in the egg in an alleviated form of typhoid, which the Russian influenza appears to be? The heat which will cook an egg will not destroy any germ. Since this suspicion has entered my head, no cheap eggs have entered the digestive system of Yours, &c.,

Rooster.

A. W. M.—Eucalyptus oil is an elegant solvent for iodine, but if any turpentine be present a very energetic combination results, sometimes amounting to a mild explosion. In the case of eucalyptus oil there is some combination so that the resulting solution does not contain its nominal equivalent of free iodine.

Mrs. H. G.—We received the notice, in common apparently with the other journals, but did not see our way to make use of it.

A Foreign Subscriber.—We do not consider that our advertising, still less our editorial columns, would be a suitable medium for calling attention to your invention, which is essentially at variance with professional ethics.

Meetings of Societies, Lectures, &c.

THURSDAY, JANUARY 4TH.

Society for the Study of Inebriety (Rooms of the Medical Society of London).—Reception to Dr. J. E. Usher, F.R.G.S., of Melborne. At 4 p.m. Papers:—Dr. Norman Kerr (President): Sir Henry James, Q.C., M.P., on The Criminal Responsibility of Inebriates.—Discussion on Opium.—Has it any use other than Medicinal? Negative:—Brigade Surgeon Pringle, M.D., H.M.'s Bengal Army.

Harveian Society.—At 8.30 p.m. Mr. Watson Cheyne: The Treatment of Breast Cancer.

FRIDAY, JANUARY 5TH.

West London Medico-Chirurgical Society.—At 8 p.m. Pathological Specimens:—Dr. Gould May: Dog's Heart containing Filaria.—Mr. L. A. Bidwell: Gallstones removed by Cholecystotomy.—Mr. R. W. Lloyd: Stricture of Sigmoid Flexure. Papers:—Mr. Maitland Thompson: A Successful Case of Craniotomy.—Dr. Lewers: A Case of Tubal Gestation Successfully treated by Abdominal Section.—Dr. Schacht: Three Cases of Ectopic Gestation.

MONDAY, JANUARY 8TH.

Odontological Society.—Annual General Meeting at 8 p.m. President's Valedictory Address. Election of Officers for the year. Mr. J. H. Mummery will bring forward a casual communication on Dr. Vicentini's recent publications on the Common Origin of the Bacteria of the Mouth.

Vacancies.

Apothecaries' Hall, Ireland.—Examiner in Medicine. Applications to the Secretary before the 12th inst. (See advert).

Eastborne Union.—Workhouse Medical Officer. Salary £120 per annum, with extras. Applications and testimonials to the Clerk on or before Jan. 4th.

Horton Infirmary, Banbury.—House Surgeon and Dispenser. Salary £60, with board and lodging. Applications and testimonials to the Hon. Secretary on or before Jan. 6th.

Ryde District.—Medical Officer. Salary £110 per annum, with vaccination fees. Applications to the Clerk's Office (Newport) on or before Jan. 17th.

Surrey Dispensary, Great Dover Street, S.E.—Surgeon. Honorarium £52 10s. Further information to be obtained from the Secretary.

University College of South Wales and Monmouthshire.—Lecturer on Materia Medica and Pharmacy. Stipend £50 per annum. Applications and testimonials to the Registrar on or before Jan. 27th.

Appointments

Atterbury, W., M.D.Irel., M.R.C.S., Public Vaccinator for the district of Akaroa, New Zealand.

Barker, T. H., M.B., Ch.M.Edin., Government Medical Officer and Vaccinator for the district of Wellington, New South Wales.

Bury, R. F., M.R.C.S., L.R.C.P., Resident Obstetric to St. George's Hospital.

Campbell, R., B.A., M.B., M.R.C.S., L.R.C.P.Lond., Visiting Surgeon to the Chester General Infirmary.

Cargill, L. V., F.R.C.S., Surgical Registrar to King's College Hospital.

Colgan, F. P., L.K.Q.C.P.Irel., L.R.C.S., L.M., Medical Officer for the Fever Hospital of the Carlow Union.

Duncan, R. B., M.D., B.S., Resident Medical Officer to the Newcastle-on-Tyne Workhouse.

Gardner, H., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer to the Chelsea Hospital for Women, Fulham.

Gassage, W. H., L.R.C.P.Lond., M.R.C.S., House Physician to the Westminster Hospital.

Griffith, J. de Burgh, M.B., Ch.M. Dub., Public Vaccinator for South Carlton, Victoria, Australia.

Hamilton, R., M.B.Lond., M.R.C.S., L.R.C.P., House Surgeon to the Chester Infirmary.

Lee, H. E., M.B., M.S.Ed., Medical Officer for Gunnedah, and Surgeon to the Gunnedah Hospital, New South Wales.

Murray, J., M.B., F.R.C.S., Surgical Registrar to the Middlesex Hospital.

Roberts, C. H., F.R.C.S., M.B.Lond., M.R.C.P., Casualty Physician to St. Bartholomew's Hospital.

Births.

Ferguson.—Dec. 31st, at 26 Woodland Road, New Southgate, the wife of R. Bruce Ferguson, M.B., B.Ch Cantab., of a daughter.

Lambert.—On Dec. 23rd, at Belgowan, Newland, Lincoln, the wife of Frederick Samuel Lambert, M.R.C.S.Eng., L.R.C.P.Lond., of a daughter.

Spokes.—On Dec. 23rd, at Ealing, W., the wife of Sidney Spokes, M.R.C.S., of a son.

Wells.—On Dec. 28th, at 3 Belsize Park, London, N.W., the wife of Poulett Wells, M.B., of a son.

Marriages.

Hewlett—Stratton.—On Dec. 28th, at Christ Church, East Sheen, Richard Tanner Hewlett, M.D., M.R.C.P., Demonstrator of Bacteriology in King's College, London, to Louise, elder daughter of Frederick Stratton, of St. Anne's, East Sheen, S.W.

Deaths.

Bentley.—On Dec. 24th, at Warwick Road, Earl's Court, Robert Bentley, formerly Professor of Botany and Dean of the Medical Faculty, King's College, London, aged 72.

Brookes.—Dec. 31st, at Camberwell New Road, Robt. Brookes, M.R.C.S., aged 78.

Wilkinson.—On Dec. 24th, at 33 Avenue Road, Grantham, Thomas Marshall Wilkinson, F.R.C.S., late of Lincoln, aged 50.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CVIII. WEDNESDAY, JANUARY 10, 1894. No. 2.

Original Communications.

THE ETIOLOGY OF THE DISEASES OF THE NOSE AND THROAT, (a)

WITH SPECIAL REFERENCE TO THEIR CLASSIFICATION AND TREATMENT.

By JOHN MACINTYRE, M.B., &c., Glasgow,

Surgeon for Diseases of the Throat, Glasgow Royal Infirmary; Lecturer on Diseases of the Nose and Throat, Anderson's College, Glasgow.

DURING the past two or three years I have given several demonstrations upon this subject, and I should be sorry to show any tendency to exaggerate a study which has proved of great interest to myself, or to minimise other branches of special work. On the contrary, I would emphasise the fact that it is the duty of each one of us to bring before the profession any new fact in any field which his experience has taught him. We must never forget that it is our first and highest duty to relieve the sufferings of those who are entrusted to our care. While it may, therefore, be useful for future advances that etiological and pathological subjects should receive our best attention, nevertheless we are daily called upon to treat our patients with the means at our disposal, and in the light of our present knowledge.

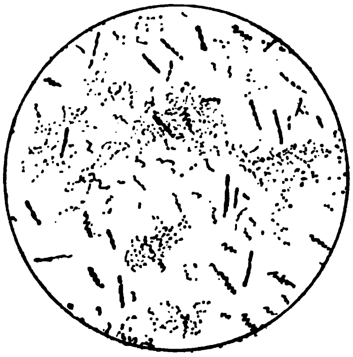
The presence of disease infers the existence of a cause or causes; that these have been brought in contact with the patient; that the tissues were incapable of resisting the invasion of the new force or forces. Again, we have in most cases to assume a deficiency in resistance of the tissues after the introduction of the causes; that certain conditions were present favourable to the existence of the new force—in other words, that more than a cause was at work; and our difficulties increase still further when we attempt to discover the exact influence exercised by each factor. Indeed, until recently it was quite impossible to obtain anything like definite knowledge of many of the most active causes of disease. I refer more particularly to bacteriological causes, which have attracted so much attention of late. Lastly, to explain the results we must discover how the causes acted so as to produce the disease. A study of etiology, therefore, involves a great deal more than at first sight appears. Some probably place too much weight upon one set of causes; for example, etiology did not begin, nor will it end, with the study of bacteriology, because, as I have said, the cause as a rule proves upon investigation not to be simple but complex. We need not only a special influence to produce a disease, but a whole series of conditions which modify or influence the true cause in the production of it. That is not all, because once the disease has been set up in the body it may become the cause of secondary pathological conditions, these again of tertiary, and so on.

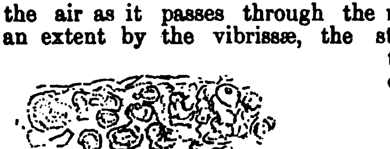
CONSIDERATION OF THE CAUSES.

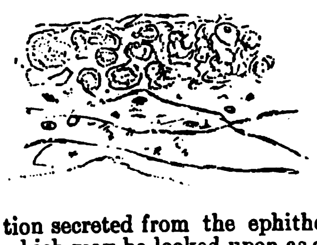
A reference to our classical text-books overwhelms one with the multitude of causes assumed to be at work in the production of disease in the nose and throat, and a careful analysis will show how difficult it is to grasp the influence exercised by each. Allow me to illustrate the difficulties by a few examples. In the production of catarrh, age, sex, and occupation are commonly quoted as factors, but occupation often infers age and sex. Again, a particular occupation may induce a certain disease, but the same malady will not affect other persons so engaged, and others not following that occupation may suffer from it. Disease is often traced to air, water, and food, but frequently these are merely vessels for the transmission of the cause, although in certain instances decay may arise from intrinsic defects in one or all of these. Again, we have change of temperature—say, cold; but cold often means, not absolute cold, but the association of other conditions, such as damp air, with movement in the atmosphere. Such terms as "poisoning" and "weak constitutions" are too indefinite to grasp; hereditary and congenital causes are constantly being quoted and often convey as little meaning. These latter, however, do not offer the greatest difficulty, because, if we could trace the production of disease in individuals, an explanation of its transmission would, in all probability, be comparatively easy. In the past, few diseases could be traced, and with the exception of foreign bodies, injuries, absence of necessary elements in food, or the administration of deleterious material, the exact causes of the vast majority were wholly unknown, unless we include such general terms as gout, rheumatism, fever, &c. Without doubt, the greatest aid to the study of etiology has been obtained from bacteriological researches. Moreover, this study promises to throw a great deal of light upon many of the factors quoted above, and whose influence could not previously be understood. For example, the study of the life-history of these organisms has revealed much about the conditions necessary for their existence; all require pabulum and a certain temperature; some require light, some heat, others air; and nearly all are influenced by the presence of other substances, which may be of an inorganic or organic nature. Thus antiseptics, on the one hand, will arrest development, if in sufficient strength and properly applied; on the other hand, the presence of certain substances facilitates their growth. The introduction of the tetanus bacillus in some animals does little harm until an organism such as the bacillus proteus be injected with it. Further, apparently harmless organisms, introduced with other apparently harmless organisms, will produce disease. The study, therefore, of the life-history of these organisms will, in all probability, throw light upon the exact influence produced by such agents as atmosphere, moisture, season, and to what extent such articles as food, water, and air are responsible for the production of disease. With a view of facilitating this study in our special department, I have added a fuller list than in any of my previous demonstrations, and I have, for the same object, brought a series of microscopic drawings and photographs before you. For example, we now know a great deal about the causes which are mainly at work in the production of inflammation, suppuration, erysipelas, lupus, tubercle, leprosy, diphtheria, and typhoid. Much has been done, more is required, because no one working in our special department can forget how many affections of the upper respiratory tract are due to constitutional affections, such as gout, rheumatism, and fevers, particularly the exanthemata, and I need hardly add, malignant disease.

(a) Abstract of Presidential Address delivered before the British Laryngological Association, December, 1893.

In a certain number of cases the causes already exist within the individual—they may be hereditary or acquired. For example, micro-organisms often lie latent in diseased teeth, in depressions in the tonsils, or the accessory sinuses, and only require conditions necessary for their development to produce disease. It has been stated that the buccal secretion is antiseptic in nature, but a careful examination of the contents will show how difficult it is to establish this proposition, for in health, even, we find many pathogenic organisms. In the accompanying figure will be seen a variety of organisms found in an apparently healthy mouth. Some of these, after cultivation and injection, produced suppuration in animals. In other instances, however, the causes are brought from without, and it is necessary to trace the channels by which they come. For the most part they are due to contact with others infected, or to such agents as air, water, food, and clothing.







In some instances this is easily enough explained, for injuries, administration of drugs, pressure upon nerves, absence of necessary elements in food, generally produce results which are clearly enough to be traced to their causes. That micro-organisms may pass from the superficial to the deeper layers of the coverings cannot be doubted; this can be seen from the next drawings given. In the first the mycelial spores will be seen passing through the epithelial structures of the mucous membrane of the nose weakened by the invasion of sarcomatous disease; and in the second drawing the spores will be seen developing within the tissues. That great protection exists in the nose and throat one cannot doubt. We have the air as it passes through the nostrils sifted to an extent by the vibrissæ, the structures within the cavities slope downwards and backwards, so that the secretions readily pass into the alimentary tract, aided by the action of the cilia; there is abundant secretion secreted from the ephithelial cells, each one of which may be looked upon as a gland capable of taking matters on the one hand from blood-vessels, and, on the other, passing it on to the surface of the membrane. Moreover, the lymphoid and connective tissues of the mucous membranes offer still further resistance; the vascular supply governing the blood-vessels and turbinated bodies is not surpassed in any other mucous surface. Consequently, obstruction or deviation from the normal anatomical conditions of the passages, weakness in the individual cells, or the nervous and vascular arrangements, and that in local or constitutional affections, must lessen the protection. Abrasions are most dangerous of all, especially if recent, and these often occur at the points of weakest resistance, say in the middle line of the lower lip, angles of the mouth, margin of the epiglottis, and the region of the fauces—in other words, where from the study of development, we know parts originally distinct and separate have become united. Again, the tissues after the invasion of the causes have further power of resistance. We need not commit ourselves to Metschnikoff's theories, ingenious and excellent as they appear to be. That the corpuscles of the blood and cells of the tissues have the power of counteracting organic mischief within the tissues no one can doubt who has studied the processes by which nature casts out that which is deleterious, or seals it up in cysts or by connective tissues cicatrisation. All these, again, mean healthy nervous vascular, and, I would add, particularly lymphatic structures for the following reasons. When chemistry has helped us still further in understanding the products of micro-organic life, it will not unlikely be found that they are by no means stable compounds; that the tissues have the power of reducing them to simpler, may be safely inferred, otherwise it is difficult to explain how recovery takes place in acute and chronic diseases. These products are carried by the blood and lymphatic system to the various organs of secretion and excretion, but it is not unnatural to assume that they may to a certain extent be split up into simpler compounds or elements within the system. If we think of how little is required to raise the temperature by injections of tuberculin—a product of bacillary growth—we are almost forced to such a conclusion, otherwise it is difficult to see how life could be preserved so long in chronic tuberculosis.

Beyond mechanical effects, comparatively little was known until very recently of the manner in which these causes acted. Doubtless many of the organic forms act by mechanical irritation, but they are most injurious in all probability from the products they produce. To learn that bacteria could produce nitrogenous waste products or poisons was the first step in advance. Panum is quoted by Brieger, our greatest authority, as being the first to isolate putrid poisons or ptomaines. Many others have since been discovered, but the works of Koch, Loeffler, Roux, Yersin, Hanken and Fraenkel are all specially interesting to us, inasmuch as they deal with the products of organism associated with the production of specific disease. We cannot, however, over-estimate facts brought out by Loeffler, Roux and Yersin by demonstrating that typical symptoms, say of diphtheritic paralysis or death, can be produced by the introduction of these toxic agents without the introduction of the organisms which produced them.

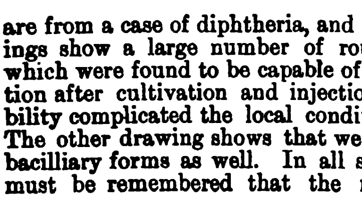
The present classification of disease in our text-books is by no means satisfactory, and a large portion of the chapters in our text-books have headings which indicate symptoms merely, such as catarrh, rhinitis, tonsillitis, abscess, epistaxis, &c. A glance, however, at special works—say, that by Dr. Whistler—or at the chapters in any of the text-books upon tuberculosis or malignant disease, show how most of these disappear when we start with a distinct or specific cause. It is then an easy matter to trace the steps of the disease in definite order and sequence. When we know more about etiology it is not unlikely the classification of disease will be made upon this basis, and the clinical evidences described under the headings of most of the chapters in our text-books will simply appear as the evidence or symptoms, or sequelæ.

The Effect of the Study of Etiology upon Treatment.

The study of etiology promises to be particularly valuable in the way of treatment. It has emphasised all that has hitherto been written upon the questions of hygiene, and the prevention of disease has been made easier by accurate diagnosis. At the last meeting of the British Medical Association at Newcastle, I pointed out the necessity for laboratories in connection with each sanitary centre where practitioners might have the benefit of a diagnosis in the earliest stages of disease, such as diphtheria. It is not to be expected that every practitioner can have the necessary apparatus for diagnosis in doubtful cases. Although the principle of inoculation remained for long one empirical fact, the experiments of Pasteur, and the researches of Koch, Hanken and others would promise something more in the prophylactic treatment of disease. Whether the inoculation of the products of micro-organisms is destined to be of great use in the prevention of specific affections remains yet to be seen. Metschnikoff's experiments would seem to throw a considerable amount of light upon what has hitherto been a great mystery, viz., by what means the tissues are protected from a second attack in constitutional fevers; and Pasteur, Koch, Liebreich and Klebs have tried to modify the virulence of the poison even after the person has been infected by the injection of certain products evolved in the life-history of particular organisms. Doubtless, although much was expected, little has been done in this direction as yet. All these, however, indicate how much is being done by our sanitary officers and experimenters in the prevention of disease.

The theory of the parasitic cause of disease naturally suggested attempts to administer agents which would destroy these active virulent causes. While it is easy to find antiseptic agents to destroy these organisms before entering into the tissues, as demonstrated in the brilliant results of antiseptic surgery, their destruction within the host is a different matter. Destruction of the parasite, as a rule, involves destruction to the individual cells of the host. In diseases of the upper respiratory tract. therefore, we have to classify all infective diseases which come in two great groups: firstly, those in which we can directly apply antiseptics, say on the surface of the membranes, or within the accessory sinuses; and secondly, those in which the causes have passed into the tissues and are beyond all hope of local treatment. In some cases, of course, both conditions may be present, and the surgeon may find it convenient to remove a local disease where a constitutional is present. In the consideration of the treatment of the first class there are still numerous fields open for research to us. For example, the best antiseptics to use in this connection. Three factors at least have to be taken into consideration in the application of a germicide: firstly, its antiseptic power; secondly, the rapidity of its action; and thirdly, how long this action continues.

It will be found that certain organisms are more readily attacked by a particular germicide than others, and consequently we have to search for the best antiseptic for the production of a particular germ. In practice, however, we must seek for some general antiseptic, because, as I have shown, more than one organism may be at work, as can be seen from the drawings here produced; these are from a case of diphtheria, and the first two drawings show a large number of round cell organisms, which were found to be capable of producing suppuration after cultivation and injection, and in all probability complicated the local conditions in the throat. The other drawing shows that we have to deal with bacilliary forms as well. In all such experiments it must be remembered that the results obtained by antiseptics outside the body are quite different from those got when applied to the same organisms within the tissues.



Both from the experimental and clinical points of view there can be no doubt that bichlorite of mercury, even in dilution to the extent of one in five thousand, is the most active in power, rapidity, and duration of time. Carbolic acid, from its many good qualities, may be classed next, and particularly on account of the fact that it is less poisonous to the patient where we have a danger of absorption. Boracic acid is not only safe, but also a very efficient antiseptic, especially when there is danger of absorption. Listerine acts with great rapidity; and thymol even in the dilution of one to fifteen hundred may also be depended upon as an efficient germicide. The action of the antiseptic varies according to its method of administration, and so we may require to select it in the fluid or dry states. In affections of the upper respiratory tract, therefore, when we are attacking this locally we may be called upon to apply a germicide for many reasons:—firstly, during or after operation to render the parts aseptic if possible; secondly, where the parts have become septic to cleanse after free drainage; but there is a third object to which I would give special attention, viz., where we wish to attack a local focus of inoculation, say, in the false membranes of diphtheria. Many agents may be used for this purpose, such as those mentioned above, and also the strong acids but a great difficulty arises inasmuch as the crypts or cavities do not allow efficient action of the germicide. For some years past I have been in the habit, after explanation to the patient, to excise the tonsils in acute affections with the view of getting the agents properly applied. While I select the example of the tonsils, the same principle applies to the other parts of the upper respiratory tract, and it likewise applies to acute diseases of an infective nature, whether diphtheritic or otherwise. I have not always been able to carry out this plan, because of objections on the part of patients and medical attendants; but where the operation has been performed, and *where efficient nursing has been at my disposal* to see that the raw surfaces were carefully and frequently attended to, I have seen nothing to deter me from making still further experiments in this direction. Some here may not believe in these being local affections, but some local manifestations of a constitutional state. In any case the principle has this merit, that the agents can be efficiently applied, and I do not see how this can be done where crypts exist in the tonsil, and into which our therapeutic agents cannot be carried. So far as our clinical observations have gone the membrane has been easily controlled upon the cut surface; there has been no elevation of temperature which one would expect if reinfection took place upon the cut surfaces, nor have there been any contrary indications from the study of the pulse, or the amount of albumen in the urine.

One of the residents in the Glasgow Belvidere Hospital, Dr. Watson, has been making observations upon this line of treatment in diphtheria at my suggestion.

No place can be better calculated for the carrying out of such an experiment as the wards of a fever hospital. I have brought with me a preliminary note of the results, and, while his only amount to eleven cases, everything I have stated above has been confirmed, and only two patients out of the eleven have died, and in one of these tracheotomy had been performed. Excision of the tonsils has been recommended in the treatment of acute affections of the throat by Browne and others. If this be recommended, great attention must afterwards be paid to the proper application of suitable antiseptics.

In the second class of disease, unfortunately, our treatment has not yet been successful, and this remark specially applies to chronic cases, such as phthisis laryngea. It is hopeless in some cases to expect much good from the scraping out and medication of an inter-arytenoid membrane, and this is easily enough explained by the affection of other organs of the body at the same time. In a case of phthisis laryngea recently under my care the inter-arytenoid membrane was scraped without any beneficial result, and this requires no explanation because such a widespread affection could not be affected by local treatment. I should be sorry to leave the impression of anything discouraging to the enthusiastic work of Professors Herying and Krause. I have, like others, had good results from local curetting of the parts, just as surgeons have had excellent results from the destruction of disease in the tarsus and carpus in cases where other organs of the body were affected, We must not, however, be discouraged by the fact that constitutional agents have not yet been discovered to combat these affections, because, after all, it is precisely in this that we have the best recent results in surgery.

Satisfactory as our results have been, we must never forget that the great majority of workers are at present dealing with the sequelæ of disease. This could not be better shown than by the study of the history of the cases in the recent great work of Professor Macewan on infective diseases of the brain and spinal cord, where we have frequent evidence of old-standing disease in the ear or throat. The same thing prevails in our every-day practice with catarrhs—even the majority of our acute inflammations are exaggerations of slumbering sub-acute or chronic conditions, probably the result of disease as far back as childhood. However brilliant such results may be, treatment of the remote pathological conditions should not satisfy us, and hence the removal of tonsils without post-nasal adenoids, or this again without the hypertrophies which produce them, must tend to recurrence and perpetuation in a considerable number of cases. In the nasal and buccal cavities, where so much can be hidden in crypts, depressions, and accessory sinuses, we cannot be too careful in our search for pathological lesions; but more than this, our experience teaches us that a large proportion of the mischief with which we have to deal could be prevented by careful nursing and treatment of those suffering from constitutional affections of childhood or adult life. Whether we are in future to have the benefit of constitution agents capable of destroying these specific organisms or not no one can say. The history of surgery in the past reveals the only means of treatment open to us at present. It must, however, be evident, with the sanitary officer on the one hand, improvements of early diagnosis, followed by prompt and thorough treatment on the other, many sequelæ of the most disastrous nature will certainly be obviated in future. The solution to the difficulty unmistakably lies in the study of etiology, and it is for that reason I have chosen this subject for consideration to-day.

In every department we see energetic workers; anatomy, microscopic and macroscopic, is being pursued with an interest and attention never excelled in the history of the past. Physiology has done much for us of late, as we can see from the works of Aschenbrandt, Fick, Block and Macdonald. Experimental physiology has also come to our aid in controlling the observations at the bedside. Although we may have a difficulty in reconciling different opinions, and without committing ourselves to any special view, we record with extreme satisfaction that our knowledge of nervous affections has been greatly enhanced by the works of Krause, Masini, Horsley and Semon. Excellent work on all hands has been done in the fields of pathology and clinical research, and these must be still further enriched by observation, although the study of medicine could never have rested on a satisfactory basis had we had nothing but clinical observation to record. One of the greatest (if not the greatest) triumphs of physical science was the prediction of the existence of a certain planet by the disturbances caused in the movements of other celestial bodies, and its discovery tested the accuracy of previous observations. So in the study of clinical medicine by the disturbances in the functions we can often infer the existence and, to an extent, the nature of a cause. The greater in number and more accurate these observations are, the surer are we to discover the cause, but after its discovery the facts relating to cause and effect will be explained and harmonised only in as far as they have been accurately recorded.

EXPERIMENTAL RESEARCHES
IN
PANCREATIC DIABETES.

By Prof. MIXROWSKI, M.D.,
of Berlin.

[FROM OUR GERMAN CORRESPONDENT]

For some time past the author has been experimenting on animals after extirpation of the pancreas, and he now publishes the results in the *Archives fur Exp. Path.*, from which I have made the following *résumé*:—

In three dogs, after complete removal of the pancreas the worst form of diabetic mellitus came on in each case. A cat also and a pig showed similar phenomena. In the case of rabbits, on account of the difficulty of total extirpation, the results were not certain. In birds and frogs there was no excretion of sugar after removal of the pancreas.

When abundant nourishment was given, the quantity of sugar was excessive, as much as 10 to 12 per cent. in a daily quantity of urine of 1 to 1½ litres. At the same time there were great variations in the amount of sugar excreted, depending to some extent in the composition of the food given. In animals that have borne the operation well, and in which every part of the pancreas has been removed, the intensity of the diabetes may remain moderate for a long time. Where carbohydrates have been completely excluded from the food, the quantity of sugar has been proportionate to the amount of nitrogen excreted, *i.e.*, it has been dependent on the changed albuminous substances in the system. There are at times other sources for the sugar found in the urine, and in respect to this glycogen has to be considered. After extirpation of the pancreas there is a rapid disappearance of the glycogen from the liver. In many cases the whole of the sugar given in the food passes out in the urine. After the diabetes has reached its highest intensity grape sugar can in no case be used up in the system.

In the last stages of pancreatic diabetes when the vital powers have become lowered the quantity of sugar excreted diminishes. This is thought possibly to be due to a diminished production of sugar or to complicated processes that decompose the sugar within the system. Even after partial extirpation a more or less considerable excretion of sugar may take place in the urine. This is important as showing that even slight disturbances of the gland may set up diabetes, and it shows further that diabetes is in direct relation to disturbances of it. A further important fact is that when pieces of pancreas are inserted under the skin and grow there the occurrence of diabetes may be prevented. Such pieces of the gland completely fill the function of the whole as far as the using up of the sugar is concerned. The secreting function of the pancreas, however, and the sugar consuming are not identical, as the gland may continue to secrete and yet diabetes may occur. This also is an important fact as bearing on diabetes in the human subject.

Sugar also occasionally appears in the urine after extirpation of the salivary glands, the quantity, however, is inconsiderable, inconsistent, and transitory.

Phloridzine diabetes does not appear to depend on its action on the pancreas, it is more likely to be produced by disturbance of the kidney function, as it was produced in birds even when extirpation of the pancreas had failed to set it up. There was another fact that favoured the view that phloridzine diabetes and pancreatic diabetes depended on different causes, viz., the difference in the saccharine constituents in the blood in the two diseases, the sugar being constantly increased in the latter 0·3 to 0·8, whilst in the former it was always abnormally low.

A study of the behaviour of the various forms of carbohydrates in the organism of diabetic animals showed that the left rotating ones were mostly used up in the system, but to a smaller extent converted into grape sugar and as such excreted in the urine. If lævulose be given in large quantities a part of it may be made to appear unchanged in the urine. In feeding with inuline there was no excretion of left rotating sugar in the urine; after feeding with cane sugar, neither it nor lævulose appeared in the urine, but grape sugar and the same after feeding with milk sugar.

It was further shown that in the diabetic system right rotating glycogen could be found in the liver and muscles part of it out of left rotating carbohydrates, but not out of those with a right rotation. Syzygium jambolanum was found to be totally inert in the form of diabetes experimented on.

NOTES ON TABES DORSALIS.

By ARTHUR DOUGLAS, M.D.

IN Tabes Dorsalis of Spinal Cord the degeneration takes place in, and is a sclerosis of, the posterior columns in the lumbar region, mostly extending from below upwards. We have good reason for believing that tabes may be present before actual sclerosis has taken place. Strictly speaking, tabes dorsalis and sclerosis are not synonymous terms; the former is descriptive of a leading clinical feature, but the latter points entirely to its morbid anatomy. Again, while the former argues the presence of the latter, yet the tracts of the posterior columns may be sclerosed without the symptoms characteristic of tabes being present.

The cause of the disease is but little known. Heredity is observable only in a very small percentage of cases. Carré records 18 cases in one family during three generations. Cases have been recorded where injury appears to be the cause. Cold is a far more probable cause. (Leyden and Leonhardt.)

Sexual excesses have been almost conclusively proved to be of no value in determining this disease.

"Foot sweat" as a cause is also *nil*, being in some cases a symptom only. E. Schulze considers typhus, intermittent fever, if only once attacked, are predisposing causes. Jaccoud thinks it often follows an attack of diphtheria. The most probable cause hitherto suggested is undoubtedly syphilis. This has been mentioned by Erb in Germany and Fournier in France, notwithstanding many cases occur where no history of syphilis can be traced.

Erb found in a given number of cases that syphilis with secondary symptoms occurred in 62 per cent., and Fournier out of 103 cases found it in 94, or rather more than 91 per cent. Vickery and Knapp, investigating in America, found 91 per cent.; by these two latter 90 per cent. was found in cases where a sore was admitted, but no secondary phenomena, a result more nearly agreeing with Erb's observation. It is interesting to note that the syphilis in these cases was of no great intensity, and it appears rare to find tertiary manifestations.

Hughes Bennett found that in cases of multiple or syphilitic tumour symptoms characteristic of tabes were present. Notes have recently been read of a case presenting all the clinical features of the disease; the post-mortem, however, showed that the posterior nerve roots were involved in a sarcomatous growth, the posterior columns being quite free.

The time from the first appearance of syphilitic symptoms to the commencement of ataxia varies from two to twenty years. It is still more curious to note that the anatomical or pathological symptoms are not the same as in syphilis.

Vickery and Knapp appear to think that syphilis generates a specific poison that attacks the nerve fibres of the posterior columns in the cord, causing no doubt some disturbance of nutrition. It is possible perhaps that syphilis may produce a predisposition to tabes dorsalis, although this is very doubtful. Zuegek found that in cases of chronic poisoning by ergot which chiefly affects unstriped muscular fibre similar changes anatomically and pathologically are produced in the cord.

The disease occurs generally between the ages of 20 and 45, and in males more often than in females.

In women a still larger proportion has been traced to syphilis. The statistics vary according to different observers. The only known cases occurring under 20 were at 18, 16, and 15, which came under the notice of Freidrich at Heidelberg.

Without entering deeply into the pathological changes, it may be mentioned that the microscope shows that the nerve cells and fibres have in places disappeared, being replaced by connective tissue from the neuroglia. The posterior nerve roots are thin and discoloured in contrast from their normal white look, the cord being of a silvery colour. The cord itself is found to be diminished in size, the pia mater thickened and opaque, with an increase in the quantity of subarachnoid fluid. The posterior columns may be seen extending the whole length of the cord as grey bands. The smallness of the cord is due to the atrophy of the posterior column. These columns lose their prominence and appear flat and shrunken, the grey colour being due to loss of medullary streak.

The posterior cornua of the grey matter show an exceptionally large amount of atrophy and look small, thin, and grey. The cord near the posterior fissure is soft and semi-translucent.

In the dorsal region the posterior columns are almost entirely degenerated.

In the cervical region the postero-internal columns are mostly affected, the postero-external also in advanced cases.

The two halves of the cord are affected in precisely the same manner, and probably, as Strümpel says, a certain system of fibres is always affected. The lesion consists of a primary degenerative atrophy of the nerve fibre and an equal amount of connective tissue, with a few fatty granular cells, and cells with many nuclei, as the process is so very slow. The membranes covering the cord are in time affected, and finally the entire thickness of the cord becomes degenerated, which degeneration may even spread to the brain substance; the spinal fluid is also much increased at times.

As the lesions are in all cases so exactly similar, so are the clinical signs, enabling a more correct diagnosis to be easily arrived at in an early stage of the disease. The symptoms are in all cases the same. A correct conclusion, however, must be arrived at as regards their intensity, order of recurrence and duration, and here there are many varieties and combinations.

The disease generally begins very insidiously, the early stages varying greatly in intensity and severity. Perhaps the earliest symptoms are sensory, marked usually by lightning pains in the lower extremities, showing that the lesion is outside the matter of the cord. These pains are also noticed in Pott's disease, and show that the nerve roots are affected: they are frequently regarded as rheumatic and treated as such; these pains may continue for a lengthened period.

In other cases the earliest symptoms are a numbness and tingling first noticed in the tips of the fingers, with muscular twitching, especially the middle and ring (Strümpell), and also the "girdle pain" this is a sense of constriction felt round the trunk on a level with the xyphoid cartilage, and is due to irritation of nerve roots in the lower dorsal and upper lumbar regions.

In other cases, again, there are neuralgic and frontal pain in the head, also an erythematous and vesicular eruption over the area of distribution of affected nerves akin to herpes zoster. There are, however, invariably two objective spmptoms which almost always appear very early even in incipient ataxia. They are—1. The abolition of the knee-jerk or patellar reflex first mentioned by Westphal. This is also a sign of multiple peripheral neuritis, a disease so similar to the one now under notice that doubtless it has many times been confounded with it. The same remark also applies to anterior poliomyelitis. It must not, however, be forgotten that in these diseases there is paralysis with muscular wasting and loss of Faradic contractility, or the "reaction of degeneration." 2. The reflex immobility of the pupil first observed and explained by Argyll-Robertson, and later by Knapp, Leber, and Hempel, *i.e.*, the pupil does not contract to light, although it does to accommodation, dilating, however, when the pain is severe; this sign is much more frequently absent than the other two. The patellar reflex is the one almost constant sign in this disease; cases have been recorded where the patellar reflex was increased. When all these symptoms are present together the diagnosis is absolutely certain, and can be mistaken for no other disease. Other symptoms noticed are diplopia due to paralysis of certain ocular nerves. Von Graafe points out the fact that ataxic patients who have this symptom show small tendency to the blending of images in binocular vision, which is supposed to point to a central origin, loss of vision from optic atrophy.

Analgesia, colour blindness, may also be present in a modified form, that is to say, he recognises yellow and black, but fails at red and green; this may lead to blindness, and is due to progressional atrophy of the optic disc. Ophthalmoscopic examination shows a chalkiness and opacity and absence of marginal rosiness of tint with inability to trace the trunks and vessels of the retina, as they appear to terminate abruptly.

In other cases, disturbance in micturition appears early, paroxysmal hæmoglobinuria sometimes occurring, and at other times the gastric crises are the first noticed.

A patient, æt. 36, complained that upon exposure to cold or chill he passed "porter coloured" urine, accompanied with a sensation of pins and needles in his hands and feet; these symptoms had on at least one occasion come on suddenly. There was no difficulty in micturition, although the quantity was less than normal, being 32 ounces: 2·6 of urea, sp. gr. 1024, cloud of albumen, no sugar, blood colouring matter present, many granular and hyaloid casts, and few renal cells; but on further examination the pupils exhibited the Argyll-Robertson phenomenon, and the patellar reflex was absent.

The second stage is called the ataxic stage, the gait becoming affected, being unsteady and uncertain, not through any paralysis of the leg muscles, but through an inco-ordination of movement. If the patient closes his eyes he immediately begins to fall; hence the difficulty in moving about in the dark. This was first noticed by Romberg. If examined in this stage sensibility to pain is found to be diminished; this was well marked in a case I examined in the Civil Hospital in Ghent.

The disturbance of micturition with pain in the urethra becomes more marked, and often cystitis is present; this condition has occasionally been treated and diagnosed as gonorrhœa. Frequently there is some improvement in this stage, but the bladder disturbance invariably returns again worse than ever. Probably the latter with the following symptoms should be classed as occasional symptoms, nocturnal incontinence, spermatorrhœa with erection, and sexual desire without erection.

The third stage is the last: the symptoms are much the same as in other chronic diseases of the spinal cord.

The patient becomes quite helpless and is confined to his bed. At times actual paralysis of the lower extremities takes places, and hence this stage is called the "paralytic stage." Pyelo-cystitis now comes on, bed-sores make their appearance, and the patient soon succumbs. A case came under my observation in which there was paraplegia, cystitis, complete optic atrophy, incontinence of urine and fæces, with bed-sores, which speedily had a fatal termination.

The ataxic gait is characteristic: the feet are thrust out and brought to the ground with a thump, and with no little uncertainty, or with what Trousseau describes as the movements of a puppet or marionette. The patient has the sensation of walking on wool, there is also a difficulty in rising from the sitting posture, the legs being widely separated, the same difficulty being experienced in maintaining a balance. Thus, ataxic patients walk with a stick, and give their undivided attention to their feet and to what they intend to do with them, Again, in Romberg's symptom this phenomenon is not ataxic, but is due to a defective control of muscular movement which is necessary to the maintenance of an equilibrium, as a result of impaired sensibility of skin and nerves at the sole of the foot, accompanied may be with perforating ulcers of foot (Strümpell). This control is supplied by the eyes, so that when the patient is watching his feet he sways very little, but the moment he ceases to look at them he loses his balance. Sometimes the ataxia appears in the upper extremities, when the patient is unable to touch the fingers of opposite hands, or to perform certain movements with his hands, such as playing the piano, writing, &c. The cause of this ataxia is by no means certain, but there are three theories worth recording:

1st.—According to Jaccoud, Cyon, and Benedict, there is a disturbance in the reflex of the spinal cord.

2nd.—According to Leyden, it is the result of sensory disturbance, *i.e.*, "sensory ataxia"; and

3rd.—According to Friedrichs and Erb, ataxia is due to a definite lesion of these co-ordinating fibres which preside over the co-ordination of muscular movement, their exact anatomical position being as yet unknown.

If Charcot places these fibres in the external portion of the posterior columns this position does not coincide with the above (3rd) theory, as these fibres do not pass through this part at all. As a matter of fact, we do not yet know the exact process of normal co-ordination. In tabes this lack of co-ordination does not imply any loss of muscular power, the patient simply, at any rate in the earlier stages, being unable to direct complicated movements, this unsteadiness being increased to a large extent by closing the eyes, which at once abolishes the power of aiding imperfect co-ordination by vision. This co-ordination is not a congenital function, but a power learned by practice. Children learning to walk are ataxic, and we ourselves are constantly learning fresh complicated reflex movements.

In order to perform these movements correctly it is necessary that all the muscles concerned should be subservient and respond with alacrity to the will. We should also be able to modify by the will the action of each muscle or set of muscles, so that its share of the work equals the amount of work to be done. A voluntary motion can only take place when all the muscles necessary for it come into no less and no greater action than is required, and when, too, they come into action at the proper time. Then if by any cause such movements are interfered with, be it ever so little, ataxic movements result; they may be either "spinal" or "cerebellar" in origin.

Duchenne was the first to show the difference between ataxia and paralysis. He clearly shows that ataxics who are unable to walk possess great strength in their legs.

Westphal, in directing attention to the connection between tabes and progressive paralysis of the insane, says that the majority of sufferers from the former disease show the usual symptoms of progressive paralysis, and as they show motor disturbance of extremities, have an anatomical lesion of posterior columns, the tabes being here a manifestation of a spread of the disease over the nervous system.

In other cases, again, the paralytic insanity is added to the spinal degeneration or affection in tabes after the latter has existed many years. Of course in the last-mentioned cases the cerebral mischief must be considered after the spinal. When this is not the case, and when there is a paralysis, an examination of the cord shows a lesion in the lateral pyramidal motor tracts in the lumbar region. The muscles of passive motion are flaccid and lack tone, the cause for which is not known, unless, indeed, we suppose that muscular tone is due to reflex origin. There is no electrical degeneration in ataxia pure and simple (Duchenne). With regard to the presence of anæsthesia, the disease must be far advanced before the patient loses the sense of feeling in the skin. There is usually present a sensibility to pain, exaggerated or otherwise. It often happens that, when the patient is pricked with a pin, he does not feel it until a few seconds later, when he may feel two "Nanye Besnau" double sensation. This symptom has been more correctly described by E. Barnak, Asthoff, Naunyn, and Heotzberg. This condition is also spoken of as a "delayed condition of painful sensation" or "delayed reflex." The senses of pressure and temperature may be found absent, or that of temperature may be normal, when in other respects there is a well-marked anæsthesia. The ataxic experiences in advanced cases also a feeling of muscular fatigue, and rigidity often comes on suddenly in various muscles, with wasting due to extension of lesion to the lateral colums and anterior cornua. Cutaneous reflexes are normal, or at times diminished, more so if sensory disturbance is present.

Dyspnœa or laryngeal crises may be present, due to spasm of the glottis or paralysis of the posterior arytenoid, which prevents opening of the glottis, and is generally accompanied with a spasmodic nervous cough (Freidrichs). The connection of this phenomenon with tabes is somewhat doubtful (Bracht). In one case where such cough and dyspnœa were present Ican found atrophy of vagus and recurrent laryngeal nerves.

The paralysis affects the abductors of the vocal cords, *i.e.*, the posterior crico-arytenoids, so that in full inspiration the glottis is only slightly opened. Occasionally there is some paralysis of the adductors, as shown by the space at posterior part during phonation, *i.e.*, paralysis of posterior arytenoid. The probable cause why the posterior crico-arytenoids are affected is owing to the anatomical fact that these muscles are supplied by the inferior laryngeal nerve, which is derived from the fibres of the spinal accessory, the nucleus of which is in the cervical cord, where the sclerosis is well marked (*vide* Case).

The pulse frequently rises permanently to 100 or 120, with habitual dicrotism (Eulenberg), and aortic insufficiency has been noticed, the cause of which is uncertain.

Sometimes the hair and nails fall off, but this is not common. Herpes may break out, and hæmorrhages into the skin and conjunctiva may occur. Charcot describes certain painless affections of joints, the alterations in which are very similar to those in rheumatoid arthritis, with the following differences:—

1. One is acute, the other chronic.
2. In chronic rheumatoid arthritis the small joints are affected, also the hip; in tabes the knee and shoulder are the usual joints.
3. In tabes there is abundant effusion with dislocation. Fractures may occur owing to the brittleness of the bones, due to a rarefying ostitis (Blun), the head of the bone becoming absorbed, perhaps owing to spread of morbid influence, to grey matter of anterior cornua, as explained by Charcot, Joffroy, and Westphal.

With regard to diagnosis, little remains to be said. Chronic alcoholic neuritis can hardly be mistaken for tabes, as in this there is an absence of ophthalmic and bladder symptoms, while atrophic paralysis may develop, which never occurs in locomotor.

In the *Birmingham Medical Review* for Sept., 1889, Dr. Suckling gives three cases in which he found typical optic neuritis in chronic alcoholic neuritis.

Similar symptoms to those described above have been noticed in those who work in tobacco factories. The symptoms of "medial tabes" consist of painful sensations, loss of patellar reflex, contracted pupil, with reflex immobility; one great difference, however, is an increase of cutaneous reflex, particularly in the lower extremities.

TREATMENT.

Owing to the disease being so extremely chronic, in fact a degeneration, and the known treatment of it so unsatisfactory, the most desirable course to pursue seems to be to engage the attention of the patient and to apply any moral remedies that we are able, at the same time adopting those methods of treatment probably only palliative, which would tend in any way to give relief to the sufferer.

With a syphilitic history, our attention would at once be directed towards anti-syphilitic remedies, inunction of mercurial ointment, half a drachm to a drachm daily, or the liquor hydrargyri perchloridi combined with iodide of potassium internally. The earlier this treatment is begun probably the greater would be the relief and benefit derived by the patient.

Electricity in its various forms has strongly recommended itself to some physicians, and apparently with some success.

When there is vesical weakness present, peripheral galvanism is found to be of use (Strümpell), one pole being applied to the perinæum and the other to the lumbar region. Rumph uses the Faradic brush with good results.

The baths of Oeynhausen and Rehme are also recommended, the patient taking a bath three or four times weekly, remaining in the water ten to fifteen minutes.

Other baths are also of use, as those of Teplitz, Medbad, Gaskin, Pfassen, and Royat. The mud and iron baths of Pyrmont, the waters of Doiburg, Cudowa, Elster, and Franzensbero may prove beneficial.

The internal administration of nitrate of silver was first used by Wunderlich, who gave one-sixth of a grain in pills taken before meals.

Ergot in grain doses three to six times a day. Possibly the ergot has an irritating effect on the nerve fibres, but does not cause them to undergo atrophy or produce "ergotism," as large doses do. Arsenic may act in a somewhat similar manner.

Phosphorus, quinine, salicylic acid, bromide and iodide of potash may also be exhibited. Prof. Eck, in Russia, found phosphorus beneficial when administered in the following manner:—¾ gr. of phosphorus dissolved in sulphuric ether and made into 50 pills with bread crumb, giving 3—6 daily.

Gower recommends cannabis indica in ¼ to ½ grain doses every four hours during the paroxysms.

The disease being so slow in its course, allows the trial of many remedies. It must not be forgotten that rest to diseased organs combined with improved nutrition are the main objects to which we ought to direct our attention.

Langenbach recommended and practised nerve-stretching with uncertain results, where special nerves are the seat of pain. This method of treatment may meet with some success; it may be due to some alteration in the circulation or to changes produced in the nerve sheath, thereby affecting the contained fluid.

Cystitis due to impaired nerve influence must be treated in the usual manner, the urine being drawn off thrice daily and the bladder washed out with some antiseptic wash.

Suspension has in some few cases appeared to give relief; in others, again, it appears to have aggravated the symptoms. The action of this treatment is thus explained by Marshall in his Bradshaw Lecture of 1883, which was based on the experiments of Victor Horsley. The latter has shown that when the great sciatic nerve is stretched it affects the sacral plexus, and thence its effects pass to the roots of the nerves, disturbing the dura mater and shaking the cord by means of the attachments of the ligamenta denticulata. In this way the ganglia of the cord are probably affected and an excitation of the vaso-motor or trophic centre is produced.

PROGNOSIS.

Although the prognosis is undoubtedly most unsatisfactory, yet from the history of cases we are inclined to think that possibly much relief may be given and the patient's life may even be prolonged and made more tolerable for the following reasons:—

1.—It is difficult in some cases to exclude peripheral neuritis, which is a curable disease.

2.—Hammond says that simple congestion of posterior column occasionally produces symptoms similar to those of tabes.

3.—Ataxy caused by syphilis may also be cured.

4.—Cases have been carefully treated in hospitals which we are almost justified in calling cured, as, for example—

A man, æt. 49, who had been ill for eighteen months with ataxic symptoms and was bedridden, was eventually able to walk about and do a little work.

Another man, æt. 38, with similar symptoms, was discharged cured, and returned to his work as a baker, which he carried on for six years.

Patient, æt. 38, complained of violent cough and dyspnœa, with sudden attacks in bed, which soon passed off when propped up. When propped up in bed his respirations were stridulous, 20 to the minute; pulse 144; no cardiac mischief.

The pharynx, after being anæsthetised by 10 per cent. of cocaine solution and examined with laryngoscope, revealed the following:—The vocal cords were seen to be slightly less white than normal; on deep inspiration they separated very slightly, while on vocalisation the approximation of the posterior third was not quite complete. There was no patellar reflex; the gait was typically ataxic. Romberg and Argyll-Robertson symptoms well marked. Fundus oculi normal. Tracheotomy had to be performed, as the distress was so urgent, but notwithstanding, he died fourteen hours after. The autopsy revealed grey degeneration of posterior columns visible to naked eye; microscopically this could be traced to medulla involving the posterior pyramid and rotiform body. The recurrent laryngeal nerve was in a state of chronic neuritis, the nerve fibres being in places obliterated by the fibrous overgrowth. This is a rare case of bilateral laryngeal paralysis from central disease. Laryngeal crises have been mentioned previously in this paper, but this is one of the exceedingly few cases where a pathological demonstration of it has ever been made, which seems rather to disprove the preceding statement of Bracht.

Touching the Argyll-Robertson phenomena, it is interesting to note briefly a few cases recorded by Dr. Turner recently:—

A. B., æt. 54, with all the symptoms of tabes dorsalis, had the Argyll-Robertson pupil in the left eye only. Fundus normal.

He also records cases of Argyll-Robertson pupil occurring in other nerve diseases in which there were no ataxic symptoms:—

C. D., had Argyll-Robertson pupil in left eye, with spasmodic closure of left lid. Tremors characteristic of disseminated sclerosis with involuntary movements of both arms.

E. F.—Argyll-Robertson pupil in left eye, with symptoms of general paralysis of the insane. Tremor of lips, facial muscles and tongue, difficult articulation, mild dementia.

G. H.—Pupils unequal. Argyll-Robertson phenomena in both eyes. Discs flat and white, vessels small. Knee-jerk normal, with no ataxic symptoms.

The causes of pupillary light reflex are, according to Dr. Turner, the following:—Structural alterations or degenerative changes occur in three situations. 1. In peripheral nerve apparatus or muscular structure of iris. 2. In afferent or efferent limbs of reflex arc, *i.e.*, optic nerve, optic tract, and anterior roots of 3rd nerve, ciliary ganglia, and ciliary nerves. 3. In central mechanism situated in and around grey matter of Sylvian aqueduct, *i.e.*, either in a group of small nerve cells in the fine part of ocular motor nucleus, or in the course of system of fibres which unite the proximal ends of optic tracts and the ocular motor nuclei. It may be further noted that as old age advances the iris, from rigidity and sclerosis of its stroma, loses to some extent its contractile power, both when light is thrown on the retina and on convergence. The fact that so many cases of tabes are syphilitic seems to indicate that the disease may be indirectly the cause of reflex pupillary immobility.

◆

ON the recommendation of the Marquis of Headfort, Lieutenant of the County, the Lord Chancellor has been pleased to appoint J. Ringwood, L.R.C.P.I., and L.R.C.S.I., Kells, to the Commission of the Peace for the County Meath.

Selected Prescriptions and Therapeutic Notes.

8. **Treatment of Lead Colic.**—Dr. Weill, of Lyons, highly recommends large doses of olive oil in painters' lead-poisoning, which he has found to succeed in every case he has tried it, when iodide of potassium and sulphur baths had been ordered; but without result. The oil is given in two ounce doses every morning. Under its use the constipation disappears and the colic with it.—(*From our French Correspondent*).

9. **Exophthalmic Goitre** :—

℞ Powdered ipecacuanha, ½ gr.;
Powdered digitalis, ½ gr.;
Ext. of opium, 1/10 gr.
For one pill, four to be taken in the 24 hours.
Iodide of potassium, } ʒj;
Tincture of iodine, }
Axunge, ℥iss.

In applications morning and evening.—(*From our French Correspondent.*)

10. **Pulmonary Catarrh** :—

℞ Arsenious acid, ⅛ gr.;
Dover's powder, ʒj;
Peru balsam, ʒj.

Divide into thirty pills, one at each repast.—(*From our French Correspondent.*)

11. **Asthma** :—

℞ Ether, ℥j;
Oil of turpentine, ʒiv;
Benzoic acid, ʒiv;
Balsam of tolu, ʒij.

To be inhaled during an asthmatic attack.

12. **Inhalation in Phthisis** :—

℞ Glycerini acidi carbolici, ʒiij;
Chloroformi, ♏viij;
Succi conii, ℥j;
Aquæ bullientis ad, ℥viij.
Misce et fiat inhalatio.

To be used twice daily.

The Practitioner.

13. **For Sore Nipples** :—

℞ Ichthyol, drachm 1;
Lanoline, „ 1¼;
Glycerine, „ 1¼;
Olive oil, „ 2½.

M. Sig. Apply. Wash off before nursing.

N. Y. Medical Record.

14. **An Electuary for Hæmorrhoids** :—

℞ Confectionis sennæ.
Sulphuris sublimati, āā ℥j;
Pulveris jalapæ, ℥j;
Copaibæ, ℥iv;
Pulveris zingiberis, ʒss;
Potassii tartratis acidæ, ʒiv;
Syrupi zingiberis, q s.
Fiat electuarium.

One teaspoonful night and morning.

The Practitioner.

15. **For Burns.**—Osthoff (*Deutsche Medicin Wochenschr.*, 1893) recommends the application of bismuth subnitrate made up with hot water into a mass having the consistency of plaster-of-Paris, and applied to the affected surface by means of a brush. In uncomplicated cases no other dressing will be required.

16. **Painful Dentition** :—

℞ Muriate of cocaine, gr. jss;
Tincture of conium,
Syrup, āā ʒij.

Rub on the gums several times daily.—Dehenne.

17. **The Abortive Treatment of Erysipelas by Ichthyol.**—Hallopeau has had good results from a treatment devised by M. Juhel-Renoy, and which consists in painting round the patch of erysipelas a mixture of traumaticin (gutta percha dissolved in chloroform) and ichthyol. On the surface of the patch he applies an ointment composed of equal parts of vaseline and ichthyol. Cure is obtained in from twenty-four to forty-eight hours.—*Progrès Médical.*

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, December 15th.

The President, Dr. Walter Smith, in the Chair.

A CASE OF MALIGNANT ENDOCARDITIS.

Dr. Burgess read a paper on a case of malignant endocarditis in a married lady, æt. 30, six months pregnant. The chief interest lay in the obscurity of the case from the first, and likewise that it differed from the description of recorded cases from its symptoms. The prominent symptoms were pain of a lightning character, shooting in paroxysms from the inside of the knee to the base of the abdomen, and a fixed pain at the symphisis; also, after a time, paralysis of the bladder. The temperature was 101°, and a murmur was apparent from the first in the mitral valves, substituted in character. Miscarriage took place on the 7th day, but as the sequela gave rise to no fresh symptoms, it was not regarded as a complication. On the 18th, embolism of the left cerebral artery occurred, followed by rapidly-increasing coma and death on the 20th day. The remarkable points were:—1. Murmur, which was present from the first, with an absence of any previous history of rheumatism. 2. The nervous phenomena, which were the distinct feature. 3. The temperature, which was of the continuous type. 4. Its difference from the ordinary forms of pyæmia—cerebral, cardiac, or septic. 5. No occurrence of emboli took place until the 18th day, and there were no signs of renal or splenic embolism the whole time. 6. The peculiar absence of sweating. The treatment was symptomatic.

Dr. Tweedy remarked that, as Dr. Burgess stated that he and Dr. Nixon at first considered the case one of hysteria, he wished to mention a case which he saw many years ago, and which he at first imagined to be one of hysteria, and which afterwards proved to be one of meningitis, as illustrating the difficulty that frequently existed in making an early diagnosis with accuracy.

Dr. Moore said that he had seen a case of a young married woman who was suddenly seized with febrile symptoms and rheumatoid pains. There was a systolic murmur; the temperature was high and variable, and there was extreme prostration. He and Dr. O'Carroll at first considered it to be a case of malignant endocarditis, but the patient subsequently got well, although for a fortnight her life appeared to be hanging in the balance.

A CASE OF THROMBOSIS OF THE PORTAL SYSTEM.

The President related the case of a young man, æt. 30, who sought advice at hospital on account of cramps in the stomach and lightness in the head, attended with shivering fits. He was anæmic; the legs were swelled, but there was no albumen in the urine, either then or subsequently. Some months later he was admitted into hospital for severe abdominal pain, which had set in thirteen days previously. He was very weak, and suffered from dry retching. His colour was sallow yellow; no leucocytosis. The abdomen was tensely distended and very tender. It was dull at lower part and sides, and fluctuation could be detected. No enlargement of the cutaneous veins. A systolic murmur was heard over the heart, at base and apex. The bowels were loose—four or five pasty motions in a day—and there was moderate pyrexia. He steadily became worse, and died in collapse, after a week's stay in hospital.

Post-mortem.—Liver normal in size, very hard and tough. Nodular cirrhosis, especially on under surface of left lobe. Gall bladder flaccid. About two and a half quarts of thin serous fluid escaped from peritoneum. Spleen enlarged and firm. Portal vein adherent to structures in transverse fissure. It was much dilated, and its coats thick (about 3 mm.) and leathery—not calcified. Its interior was occupied by a firm yellowish granular thrombus adherent at one side to the veins, but not completely obstructing its lumen. Branches of portal vein through the liver filled with soft thrombi, closely fitting, and yet capable of being withdrawn. Mesenteric veins occluded by soft red thrombi. The jejunum, for about one foot, was adherent to ascending colon by soft recent lymph. There was acute recent peritonitis over liver and over this portion of the bowel, which was intensely congested, and nearly black, resembling a strangulated intestine. No blood in its interior; mucous membrane eroded. The walls of the rest of the small intestine much thickened by œdematous swelling. Several veins near pyloric end of stomach firmly thrombosed. Pleural adhesions existed on each side, and there was effusion into the right pleural cavity. The probable order of events was—(a) cirrhosis of liver, (b) thrombosis of portal vein, (c) sudden extension of thrombosis to gastric and mesenteric veins, (d) peritonitis.

Dr. **TWEEDY** said that at present there was under his care a woman suffering from ascites. Laparotomy had been performed three months previously. She has been tapped eight or nine times within the last three months, and last time he drew off more than 400 ounces of fluid. In the absence of any evidence of hepatic or other disease likely to cause the ascites, he made a provisional diagnosis of adhesive pyle-phlebitis.

Dr. **BEWLEY** said he had seen two cases of thrombosis of the portal vein. In one, the patient suffered from cirrhosis of the liver and dropsy, and also a good deal of abdominal pain. An autopsy revealed a rather soft clot in the portal vein without any involvement of the mesenteric veins. The second case was that of a man suffering from vomiting, pain, and distension of the abdomen. The bowels were obstinately constipated and a laparotomy was performed. About one foot of the small intestine was found to be in much the same condition as in Dr. Smith's case. There did not seem to be obstruction to the passage of matter through it. The man died shortly afterwards, and at the post-mortem it was found that the mesenteric and portal veins were thrombosed, as well as some of the deeper veins of the abdominal wall, where the laparotomy incision was made.

The **PRESIDENT** replied.

The Section then adjourned.

◆

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, JANUARY 3RD, 1893.

The President, Dr. G. E. **HERMAN**, in the Chair.

SIX MORE CASES OF PREGNANCY AND LABOUR WITH BRIGHT'S DISEASE.

THE PRESIDENT contributed a paper containing notes of six further observations of pregnancy and labour associated with Bright's disease. He compared these cases with others reported in former communications by him to the Society, in all eleven in number, and then compared these eleven cases with twelve cases of puerperal eclampsia, also published by him in the Society's Transactions. He drew the following general conclusion:—There are at least two kinds of renal disease to which a pregnant woman is specially liable. One of these is a very acute disease, in which premonitory symptoms are either absent or of duration measurable by hours or days. It attacks chiefly primigravidæ. It often causes intra-uterine death of the child. It is attended with extreme diminution of the quantity of urine, and the small quantity of urine that is passed is greatly deficient in urea, but contains enough albumen to make it solid on boiling. This disease is accompanied with rapidly recurring fits. If it run a favourable course, the fits cease, then the urine increases in amount, and the percentage of urea in it rises. If the excretion of urea be not re-established, the case quickly ends fatally. Such cases seldom, if ever, pass into chronic Bright's disease. The other is a disease which attacks older subjects, chiefly those who have had children before. Its premonitory symptoms extend over a period measurable by weeks or months. It often leads to intra-uterine death of the child. It is accompanied generally by increase in the quantity of urine, with copious loss of albumen, but not so much in proportion to the urine as in the more acute disease, and with diminution in the elimination of urea, but not nearly so great a diminution as in the more acute disease. Delivery is followed by temporarily increased diuresis and increase in the urea elimination. When this increase is considerable, the albuminuria usually diminishes and disappears, and the patient gets well. When the increase is only slight the albuminuria persists, and the case becomes one of chronic Bright's disease. This form of disease is sometimes attended with fits, but generally not. The presence of albuminuric retinitis affects the prognosis unfavourably. When the pressure within the abdomen is greater than usual, the amount of urine may be diminished, but in such cases the diuresis and the augmentation of the urea elimination after delivery are proportionately greater. In the acute disease which causes eclampsia, and in the chronic disease when it is associated with excessive intra-abdominal pressure, much of the albumen is paraglobulin. The cases in which the albumen is mainly serum-albumen generally either die or pass into chronic Bright's disease.

Dr. **ARTHUR GILES** observed that what was wanted was rather a grouping of the numerous facts with a view to their proper understanding than any further facts. He pointed out that there is a certain parallelism between the two forms of kidney affection described by the author in association with pregnancy and labour, and the acute and chronic forms of kidney mischief met with independently thereof. He had never met with a case of eclampsia without the presence of albumen in the urine, although he could conceive that under certain circumstances the kidney might be involved to such an extent that the albumen might be unable to find its way through.

Dr. A. **ROUTH** said that it was in the minor rather than in the more severe cases that paraglobulin was found in the urine contrarily to the view put forward by the author. He remembered two cases of albuminuria in unmarried young woman, one of whom was in the fifth, and the other in the seventh, month of pregnancy. One girl had severe epigastric pain (an important prognostic sign) with sub-retinal hæmorrhages. In the other the head symptoms were most marked. In the girl who was in the seventh month of pregnancy the paraglobulin amounted to about half of the albumen present in the urine, while in the other it constituted but an infinitesimal proportion. The fifth month patient had eclampsia, although there was but a very small proportion of paraglobulin in her urine.

Dr. **DUNCAN** referred to two cases of albuminuria in pregnant women. In both there was intense albuminuria with albuminuric retinitis. Dr. Cayley had consulted him in reference to one of them as to the propriety of inducing premature labour in view of the fact that the patient's eyesight had been steadily getting worse. He emptied the uterus and both the eyesight and the retinitis subsided. In the second case the patient was twenty-five years of age, and had had several children, with one miscarriage. She became pregnant for the third time at the end of 1892, and was delivered of a dead child in January, 1893. Shortly after quickening there was swelling of the eyelids, legs, &c., with progressive failure of vision. She became almost blind, but within two days after delivery her condition began to improve, and within three weeks she was all right again. She was admitted on September, 1893, again pregnant, and completely blind, even to the loss of perception of light. Sight had begun to get dim four or five weeks before, and had culminated in the actual condition of blindness within three weeks. Examination of the eyes showed the existence of extensive albuminuric retinitis. Although he promptly emptied the uterus the eyesight did not improve, and five weeks later she was discharged at her own request in the same condition. He insisted on the fact that the treatment of albuminuric retinitis associated with pregnancy was a very important question, one too which had not been touched upon by the author. He admitted that cases were met with of albuminuria during pregnancy in which no trouble either during pregnancy or labour resulted, but he urged that when the case is complicated with albuminuric retinitis the indication was to empty the uterus forthwith.

Dr. **Horrocks** said he was unable to remember any case of recovery when albuminuria was associated with albuminuric retinitis though he could recall several that had terminated fatally. The complication was, therefore, of considerable prognostic importance. He pointed out that cases in which there was albuminuric retinitis with subretinal hæmorrhages were necessarily grave, because the existence of such lesions proved the severity of the constitutional condition. He suggested that it would be easy for all of them to verify the author's observations as to the gravity of the prognosis in the cases in which the excretion of urea was not promptly re-established after delivery. He urged that the fits which occurred during pregnancy or labour apart from albuminuria belonged to a different category. Such cases usually got better rapidly and the fits moreover were amenable to bromide of potassium.

The **President**, in reply, pointed out that there was a great difference between the two conditions of kidney affection observed during pregnancy and the forms of renal disease met with independently thereof. He said there was no form of the disease unassociated with pregnancy which would determine fits within so short a time of the onset or in which symptoms of such gravity went off with such remarkable rapidity when the uterus was emptied. He pointed out that after death from puerperal eclampsia marked lesions of the kidneys were often conspicuous by their absence. He agreed with Dr. Duncan that labour ought to be induced in cases complicated with albuminuric retinitis. He even went further and urged the same course in all cases of pregnancy complicated by really severe albuminuria in order to minimise the danger to the patient of the supervention of chronic kidney disease. He added that under any circumstances eclampsia involved considerable risk to the child's life *in utero*. He objected to the same term being used to designate the fits associated with, and those occurring independently of, albuminuria. The term eclampsia ought, he urged, to be restricted to diseases of the kidneys in pregnant women accompanied by fits. Ordinary fits occurring during pregnancy or labour might be described as "fits without albuminuria."

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, Jan. 5th.

The President, Dr. **Donald Hood**, F.R.C.P., in the chair.

The following pathological specimens were shown :—

Mr. R. H. **Lloyd** : A stricture of the sigmoid flexure.

Dr. **Gould May** : A boy's heart containing filaria from Fiji. These gave rise to no symptoms except cough, and do not appear to shorten life. They grow 5 inches in length, and are not found in the human being.

Dr. **Maitland Thompson** : A successful case of craniotomy. Patient a primipara, æt. 26, only 4ft. 10in. in height, had been in labour 48 hours, os partly dilated and membranes ruptured ; rachitic pelvis, conjugate diameter 2¾in., transverse 4in. ; forceps were of no avail ; perforation was performed, and the skull bones entirely removed, evisceration and dismemberment subsequently were necessary, the whole operation taking four hours. The case did extremely well, the patient getting up on the 20th day.

A CASE OF TUBAL GESTATION SUCCESSFULLY TREATED BY ABDOMINAL SECTION.

Dr. **Lewers** : The patient suffered for a short time with vaginal discharge and iliac pains. On April 1st she also had sickness and more pain, the vagina and cervix were bluish, and the breasts full. There was fulness to the right side of the uterus which was enlarged.

On April 10th she had severe pains and vomiting. The uterus was examined and found empty. Abdominal section was performed on April 22nd. Blood clots of various ages and a three months' fœtus were lying among the intestines ; the right tube was perforated anteriorly, and also a second rupture posteriorly. The tube was removed, toilet of the peritoneum performed, iodine water, tr. iodine ʒj. to the quart being used, one week later stitches removed and pulse rose to 140, temp. 102°, with swelling of salivary glands, a few days later there was a discharge from the wound which healed again shortly. There was no distinct history of amenorrhœa. Previous exploration of uterus advocated where possible, and Dr. Lewers was of opinion that the loss of blood was spread over several days.

FOUR CASES OF ECTOPIC GESTATION.

Dr. **Schact**. Two under himself and two under Dr. **Travers**. No. 1.—Seventeen days before admission pain in abdomen and faintness, followed by two similar attacks. On admission tumour was felt in right lower abdomen, mass occupied right fornix and Douglas' pouch ; abdominal section performed ; a two and a half months fœtus and tube (right) removed. No 2.—Six weeks before admission patient was seized with abdominal pain and vomiting. Four weeks later a brown vaginal discharge commenced, which persisted until admission. Right lower abdomen tender, tumour to the right of uterus. Abdominal section ; right tube distended, which was removed, as was also the left on account of hæmorrhage from a point previously adherent to the right tube. The left tube was the seat of an unruptured tubal pregnancy. No. 3.—First symptoms seven days prior to admission, pain during last five days. The left appendage was the seat of the trouble in this case. The symptoms were very marked, and the operation was, as in the two previous cases, successful. No. 4.—This was considered probably pyo-salpinx, but was also tubal gestation, rupture taking place in the seventh week. Abdominal section was successful here also. There were two symptoms common to all, hæmorrhage irrespective of the period and irregular pain ; in two a pulsating vessel was distinctly felt at the lower part of the mass per vaginam.

Dr. **Maitland Thompson** recorded a case of a fœtus weighing 4½ lbs. being removed by the late Dr. Mathews Duncan from a case of his.

Dr. **Travers** spoke warmly in favour of abdominal section even in apparently almost hopeless cases where there was fair reason to suspect ectopic gestation.

Dr. **Lewers** advocated exploration of uterus in these cases.

Dr. **Schacht** considered this unnecessary as enlargement of the uterus was by no means always present.

Paris, Jan. 6th.

Micro-Cephalic Idiocy.

When Prof. Lannelongue, twelve years after the operation of craniectomy performed by Füller for idiocy, and never repeated, had communicated in 1890 to the Academy of Sciences, the fortunate result of a similar operation performed by him on a little child of four years he met with an enthusiastic reception. Restoring the intellect to idiots by removing a strip of the cranium in order to give room to the brain to develop normally was truly well imagined. The history of this case stimulated other surgeons and cases became multiplied. At the Surgical Congress of 1891 Lannelongue presented twenty-five new cases with only one failure. However, when the first emotion had passed, surgeons became more sceptic as to the advantages in an intellectual point of view of the operation, and many even opposed it strenuously, alleging that it was the brain which made the osseous envelope, moulding it to its own shape ; that premature ossification of the sutures does not exist, and in any case degeneration of the brain substance co-exists with deformity of the cranium. In spite of this criticism, craniectomy is capable of rendering real services in certain well defined and well chosen cases.

Dr. Blanc, a rising surgeon in the populous town of St. Etienne, has just reported the results of three cases operated by him, which I briefly *resumé:*

CASE 1—Boy, æt. 7, very small head, a complete idiot, extremely agitated, screaming continually, can neither stand nor walk alone. He was operated on in October, 1891. By the aid of the trephining instrument an opening was made in the direction of the sagittal suture, four inches long and one inch wide. The immediate result was very satisfactory, the agitation disappeared as if by enchantment, and the child shed tears like any other. Signs of intelligence were also witnessed. However, after a short time all the old symptoms returned, but less accentuated, and finally another improvement took place and has since been maintained. He is now but little excited, is obedient, understands better, says a few words, and walks alone.

CASE 2.—A child, æt. 3, a complete idiot, recognised no one, not even her mother, frequent convulsive cries and chronic spasms. Craniectomy performed November 1891. Six months ago her condition was much improved. She understood when spoken to and recognised her parents, but the spasms and cries continued.

CASE 3.—Boy, æt. 5. Devoid of all intelligence, never spoke, head very small, could not stand. Eighteen months after the operation his condition satisfactory. He could say some words and stood up alone. His mother seemed to be greatly pleased with the progress made.

In commenting on the above and similar cases, Dr. Blanc rightly said that in operating thus on microcephalic children, it is not pretended to be able to transform these afflicted beings into orators or statesmen, but to improve even in a small measure, their sad condition. If that end can be attained, the operation is not only justifiable, but humane.

PROPHYLAXIS OF FLOATING KIDNEY.

At the meeting of the Société Medicale des Hopitaux, M. Le Gendre spoke on the mode of production and the prophylaxis of floating kidney, and said that the theory of Bouchard who explained nephroptosis by the fact that persons suffering from a dilated stomach have frequently enlarged liver, and this organ would bulge out the false ribs on the right side if it were not for the constriction produced by the corset in the woman and that by a belt which some men wear; the liver not being able thus to extend itself excentrically, flushes down by degrees the abdominal viscera, and among others first the kidney had been corroborated by his own observations. All these circumstances are, however, but predisposing, to which might be joined a certain hereditary weakness of the abdominal walls; a shock or a fall is required in most instances to transform the displaced kidney into floating kidney. As to the prophylaxis, he would recommend the disuse of rigid corsets to girls suffering from agony of the gastro-intestinal tract, and the administration from time to time of a little strychnine. An abdominal elastic belt is often required in young women after a confinement or an abdominal operation.

M. Frantz Glénard said that out of 4,215 patients he found a floating kidney in 537, the very larger portion being women (88 in every 100 cases), and the right renal organ was found to be the most frequently displaced. Floating kidney is only found in patients suffering from gastric troubles.

COMPULSORY NOTIFICATION.

The following diseases are ordered to be notified by the attendant, to the sanitary bureau or the mayors of all the districts in France, after 15th January:—1. Typhoid fever. 2. Typhus. 3. Small-pox. 4. Scarlatina. 5. Diphtheria (croup). 6. Cholera. 7. Plague. 8. Yellow fever. 9. Dysentery. 10. Puerperal affections. 11. Ophthalmia neotomur. The malady is to be indicated by its number on post cards furnished gratuitously by the authorities to the doctors. These cards are sent unstamped to the Mayor or the Prefect, through the post.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan 5th.

SCHOOL MEDICAL OFFICERS.

IN my last it was mentioned that Dr. Weyl was an advocate for the appointment of medical officers to schools, and I promised to return to the subject. There are two ways of looking at children. From one point they may be considered as exclusively the concern of their parents, upon whom all responsibility for the maintenance, education and care in sickness rests. From another point of view, however, they may be considered in their relation to the State. If they are brought up viciously they will become a constant expense and annoyance to their fellow citizens, and if their health is neglected or undermined they will, in all probability, become equally a burden to the State from inability to work, unless maintained by their relatives. The State, therefore, has a pecuniary interest in the moral training of its youthful citizens, and one not a whit less in the sound condition of their bodily health, and this interest ceases only with the interment of the individual. From this point of view it seems not unreasonable that School Medical Officers should be appointed. Dr. Weyl is a strong advocate for such appointments, in the expectation that through them the hygienic requirements of schools will be better fulfilled than they are at present. School Medical Officers have already done a good work in many cities in tabulating the statistics of disease amongst school children. In the middle schools of Stockholm, for instance, 40 per cent. of all the scholars were found to be affected by some chronic disease, tuberculosis, or disease of the eyes or ears. 13 per cent. of the boys suffered from habitual headaches, 13 per cent. of the girls from chlorosis, and from 2 to 3 per cent. of the scholars from affections of the lungs.

In the schools attended by the better-to-do-classes 17 per cent. of all children in their 8th year were ill. In their 2nd school year 38·7 per cent., and in their 4th school year 40 per cent. were the subjects of some chronic disease. These figures are based on data furnished by the well-known axel key. In Berlin the "Magistrates Commission" for the year 1890 gives the following: with a population of 1,570,000 there were 200,000 children attending school, of whom only 1 per cent. were over 14 years of age. Of this number 1,014 children died between the ages of 6 and 14, 150 of diphtheria, 191 of pulmonary tuberculosis, and 33 of inflammation of the lungs.

Dr. Weyl further points out that a larger part of all epidemics are school epidemics. This extension could be put a stop to at once if the schools were closed at the proper time and the schoolrooms were disinfected. The author does not sigh for an official who shall be the autocrat of the school, but rather desires one who shall labour in conjunction with the teacher, and he suggests that the object might be attained by the appointment of the ordinary poor-law medical officer to perform the duties.

COLLECTIVE INVESTIGATION ON INTUBATION AND TRACHEOTOMY.

This report was submitted to the 65th meeting of the Naturforscher and Aerste at their last meeting.

Prof. V. Ranke, of Munich, said that the inquiry covered four years, that embracing the two first years being published in the *Munich Med. Wochensch.* The years 1892-93 gave 721 cases of primary diphtheritic stenosis, with 37·6 per cent. of recoveries after intubation, 55 cases of secondary diphtheritic stenosis (after measles, &c.), with 39 per cent. recoveries also after intubation. Intubation was performed when otherwise tracheotomy would have been indicated. The secondary diphtheritic stenosis after measles, scarlatina, croupous pneumonia, gave in the four years 121 cases with 22·3 per cent. of recoveries. The total gave 1,445 cases with 37·5 per cent. of recoveries. Primary diphtheritic stenosis that were first "intubirt" and later on tracheotomised were 242 in number (18 per cent. of all the intubation cases) with 8·2 per cent. recoveries. Secondary 8 cases with no recoveries, these were almost without exception cases of descending diphtheria.

Hr. Wiederhofer, of Vienna, primarily intubed in mild and severe cases, removed the tube tentatively after twenty-four hours, then performed tracheotomy when after passing the tube four, and at the most five times, dyspnœa continued. If the stenosis was very severe tracheotomy was performed at once. He had obtained the following results:—

In 1890 132 cases were intubed with 57 per cent. recoveries. In 1890 in 78 cases tracheotomy was performed with 23 per cent. recoveries, making a total of 210 cases with 47 per cent. recoveries.

1891	Intubed	147	cases, with	81·63 p.c. recoveries.
	Intubed and tracheotomised	69	,,	26·08 ,,
	Trachootomised only	58	,,	130·8 ,,
	Total	274	,,	53·28 ,,

Prof. v. Ranke recommended intubation in the country where assistance could not be procured and where there was dread of cutting operations, and alluded to Heubner's laryngeal phantom illustrated in the *Jahrbuch der Kinder Heilkunde*, on which the operation could be learned and practised. As regarded tracheotomy the figures for the four years were 1,118 primary stenosis with 38·9 per cent. recoveries, 42 secondary stenosis with 26 per cent. recoveries, these nearly approaching the results of intubation. Intubation in the two first years of life, however, gave far more favourable results, as had been remarked in America.

Collective investigation gave the totals:—

In the 1st year	55	tracheotomies	with	5·5 p.c. recoveries.
,, 2nd ,,	212	,,	,,	25·4 ,,
,, 1st ,,	93	intubations	,,	13 ,,
,, 2nd ,,	285	,,	,,	32·3 ,,

The conclusion to be drawn by therapeutics from the statistics was that by a proper selection from both methods of treatment the percentages of recoveries should be raised, and for this there was a well grounded hope. Diphtheritic stenosis in the two first years of life, as well as the milder and mid-severe cases were more suited for intubation, as here a cutting operation was to be dreaded partly on its own account, and partly because the illness would be of a shorter duration if avoided. In stenoses lasting longer (over five days) subsequent tracheotomy was called for to avoid decubitus. In cases of sudden asphyxia when a tube was in position tracheotomy was justifiable, although the withdrawal of the tube would often be sufficient as it assisted the expulsion of membrane by coughing. Difficulties in giving nutriment when the tube was in were now rarely observed, and scarcely ever rendered tracheotomy necessary. In descending diphtheria both operations were about equally powerless.

ANTHRAX INFECTION IN BRUSH WORKERS.

During the past three years about thirty cases of anthrax have been observed amongst the brush workers in Nuremberg. In most of the cases the disease was of the external kind, or malignant pustule, which with early operation was recovered from; in three, however, it was of the internal or intestinal kind, and all died. The question has been debated whether the virus present in the raw material cannot be destroyed before work people are allowed to handle it. The present mode of disinfection which is fairly good but not absolutely reliable is as follows:—The brushes lie for twelve hours in an aqueous solution of permanganate of potash, they are then well washed out with water and placed for two hours in a 3-100 solution of sulphuric acid, lastly peroxide of hydrogen, or ammonia is added to the acid solution, and the brushes are then washed out well with water. That the virus adheres mechanically is shown by the fact that nearly all of it is removed by the centrifugal cleaner.

Austria.

[FROM OUR OWN CORRESPONDENT]

VIENNA, Jan. 5th, 1894.

UTERUS DUPLEX BICORNIS.

At the Gynæcological meeting Prof. Weinlechner gave the history of a patient whom he desired to show to the meeting, but who had refused to come forward at the last minute. She was æt. 28, and had been treated at several ambulatoria for swelling of the adnexa, fluor albus, &c., before falling into his hands. On examining the vagina he discovered a firm membrane dividing it into two equal parts, into which two fingers could be introduced and the septum lying between. On further examination with the sound the uterus was also found to be double; the left being normal in length while the right only measured two centimetres in depth. Both the uterine halves were firmly united to one another in the middle portion, while the portiones vaginales and fundi of the uteri were turned outwards. The left Fallopian tube could be felt thickened, resembling the little finger, tender, with the ovary greatly enlarged. The right adnexa seemed normal. Weinlechner said that hitherto only three such cases had come under his notice as normal abnormalities, a fourth complicated with atresia—while a fifth occurred in a new-born child. In two of the cases which Weinlechner had examined with Prof. Lang, the duplicate part of the vagina was imperfectly formed, the septum being crescentic, the uterine halves parallel and of normal length. In this case as the foregoing, the left side was wider and the portio better developed. The third case had the septum resembling the first case described, and the left vaginal portion similar to all the others. Both horns of the uterus became gravid at different periods. He attributed this condition to mere accident in cohabitation.

Concerning the newborn, which was a female, it was observed that no stools were passed. One opening through which a catheter passed entered into the bladder or a large cavity behind. Before operation was undertaken the child died. The post-mortem revealed a large cloaca or expansion of the descending column, into which the bladder emptied itself, and was finally discharged into the single opening.

Weinlechner proposed the extirpation of the ischial bones and opening of the rectum, and after examination determined on final operation. In cases where this is inapplicable an *anus præternaturalis* should be made.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Intracranial Neurectomy of the Fifth Nerve—Krause's Operation.—Mr. **Rose**, assisted by Mr. Carless, operated on a man, æt. 69, who for years back had been subject to intractable neuralgia of the fifth nerve on the left side. The patient had formerly been under treatment at another hospital, where the third division of the fifth nerve had been divided just outside the foramen ovale by Horsley's method of deepening the sigmoid notch; temporary improvement had resulted, but the patient was at the present time in a most pitiable condition, and had twice attempted to commit suicide; he was, therefore, willing to undergo any operation which held out a prospect of relief. The head was shaved, the conjunctival sac on the affected side purified with 1 in 2,000 sublimate lotion, and the eyelids of the same side stitched together with catgut suture. An omega-shaped incision was made, commencing about an inch behind the external angular process of the frontal bone, carried upwards as high as the temporal ridge, and terminating about an inch and a half above the external auditory meatus; this incision was carried down to the bone, the periosteum over which was incised and reflected slightly on either side; the temporal muscle had entirely disappeared, owing to the atrophy set up in it by the former operation. The bone itself along the line of the incision was now divided by means of an angular chisel, a trephine opening having in the meanwhile been made at the upper part so as to ascertain the thickness of the skull; an elevator was next passed under the upper border of the divided bone and the whole osseous flap attached to the skin and subcutaneous tissue prised up and turned downwards after fracture of its base; the dura mater was thus exposed with the anterior branch of the middle meningeal artery coursing over it; blood welled up from below between the bone and dura mater, evidently from the main trunk of the same vessel. The periosteum and structures in the temporal fossa were now stripped off from the outer aspect of the bone at the lower part of the wound below the line of fracture so as to allow removal of the base of the great wing of the sphenoid and of the squamous bone, thus opening freely the floor of the middle fossa of the cranium. The dura mater was separated from its attachments to the base of the skull by the use of instruments and of the index finger, and the brain enclosed in its dural sheath gently lifted up and held aside by retractors so as to expose the structures at the outer aspect of the cavernous sinus. The foramen spinosum was seen and plugged with a small portion of sponge so as to control the hæmorrhage from the meningeal artery, and the second and third divisions of the fifth nerve were traced forwards from the situation of the Gasserian ganglion to the foramen rotundum and foramen ovale respectively. The root of the fifth nerve was now sought for where it passes over the apex of the petrous portion of the temporal bone into the cavum Meckelii, a small cutting hook was passed round it in this situation and the root thus divided. The central end was next caught in a pair of fine forceps and the root extracted from the pons, a portion about 2 centimetres in length coming away. It was decided not to interfere with the ganglion itself, nor with its branches. The exposed structures were carefully washed, the portion of bone which had been turned down replaced in position, and the wound closed by sutures, a drainage tube being placed in the posterior angle. Mr. Rose remarked that this operation had been devised independently both by the American surgeon Hartley, and by Krause, of Altona. Seven or eight cases, he said, had been already recorded, and he felt it only just to give it a trial.

UNIVERSITY COLLEGE HOSPITAL.

Exploration of Kidney for Stone—Negative Result.—Before operating on a middle-aged man who for some time had suffered from symptoms of stone in the left kidney, Mr. **Barker** remarked that he confined himself to saying that probably a stone was present, although the symptoms might exist and yet no stone be found; even then he thought it still perhaps might be there, as a small calculus was sometimes most difficult to find in the kidney. The symptoms had been blood and pus in the urine, and the characteristic pain which was increased on exertion. Whilst under observation, flushing out by taking large quantities of distilled water had produced intervals of comfort, but on the patient getting about again the pain had returned and incapacitated him from working. The operator said he proposed to explore the kidney by an oblique incision between the last rib and the crest of the ilium across the outer border of the erector spinæ, and drew attention to the importance of letting a very fat subject like the present patient become completely anæsthetised, as the difficulties of the operation were increased by any gasping or straining. Mr. Barker made an incision about three or four inches long, and the parts being held asunder by retractors, first explored the outside of the kidney and then made an incision into the organ itself, remarking that this often caused free hæmorrhage, which was generally stopped by the introduction of the surgeon's finger; in the present instance the bleeding was not as copious as was expected. On entering and exploring the pelvis of the kidney, he pointed out that it was possible, if sufficient care be not exercised, to entirely miss the pelvis by going through the cortex and on to the convex portion. However, complete examination failed to reveal the existence of any stone in the present instance; this, Mr. Barker said, had happened to surgeons several times of late. He drew attention to the fact that several conditions other than that of stone may give rise to the symptoms of the latter: for example, a very small crystalline deposit may be enough to cause hæmaturia and pain, but yet cannot be felt by the surgeon; again, tubercular ulcers may exist in the pelvis of the kidney, as happened in one of the first cases operated on years ago at University College Hospital; again, certain conditions of fibroid kidney which are painful may yield pus or blood without a stone being present: as an example of this, he quoted the case of a member of the profession who was going to be operated on for stone in the kidney, but for some reason the operation was put off, and years afterwards, at death at an advanced age, the kidney was found to have been fibroid, but no stone existed. Still he thought that in the present case as in all others there might still be a stone which had been missed by the surgeon. He closed the wound and employed no drainage tube, remarking that it was unnecessary, as all hæmorrhage had been completely arrested.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 10, 1894.

THE TREATMENT OF SEVERE ALBUMINURIA ASSOCIATED WITH PREGNANCY.

IN a paper read at the last meeting of the Obstetrical Society, Dr. Herman concluded a valuable series of observations on albuminuria associated with pregnancy and labour. Every practitioner who observes his cases must have noticed that there are at least two main groups of kidney disease in this association. Albuminuria in a more or less marked degree is a very common complication of pregnancy, but in a large proportion, the majority, of the cases it does not lead to any of the graver symptoms to which pregnant albuminuric women are liable. In a certain number of such patients, however, not only is the disease acute in its onset and violent in its manifestations, but we get the dreaded eclamptic convulsions which threaten the life of the mother and jeopardise that of the unborn infant. The risks dependent upon the renal disease are then, first the life of the mother, secondly that of the fœtus, and, lastly, the danger of the acute phase giving place to a chronic form of Bright's disease after delivery. The main points which still call for discussion are the means of distinguishing between the cases which are likely to comport a grave sequel and the best method of obviating the danger of usual defects and renal disease as a sequel. Dr. Herman tells us that the acute form attacks mainly women who are pregnant for the first time, and he points out that when the albumen in the urine consists mostly of serum albumen the prognosis is grave. It is, therefore, necessary for the practitioner to accustom himself to testing for the presence of paraglobulin as compared with serum albumen. One of the common symptoms associated with the albuminuria of pregnant women, as in albuminuria from other causes, is failure of vision, attributable to the presence of albuminuric retinitis, and possibly sub-retinal hæmorrhages. In the graver cases this may go on to complete loss of perception of light. Although in most cases the cecity passes off more or less when delivery has been safely accomplished, this is by no means always the case, and the preservation or protection of sight becomes one of the points to which treatment must be directed. Now the treatment of the albuminuria of pregnant females is practically confined to the induction of premature labour. As soon as the uterus has been emptied the symptoms usually promptly subside ; indeed, the promptness of this subsidence is one of the most remarkable features of renal disease associated with pregnancy. The speakers in the discussion that followed accepted this conclusion, and did not hesitate to recommend that the uterus should be emptied forthwith in all really serious cases of albuminuria associated with pregnancy. The child is sacrificed, it is true, but its chances of survival in the presence of eclampsia, or even of severe albuminuria, are small indeed, so that this fact cannot and ought not to be allowed to weigh in the balance, especially as the mother is thereby rescued from one of the most terrible complications that can threaten the pregnant woman. Then, too, in the cases presenting indications of albuminuric retinitis. These are always severe cases, and most of them die if left unrelieved. Moreover, the further the case is allowed to go on the greater is the damage done to the delicate structures of the eye, and the greater are the risks of permanent impairment of vision. This is a serious point well worthy of consideration, and in future obstetricians will be well advised if they adopt the suggestion to empty the uterus as soon as, at latest, ophthalmoscopic examination reveals the familiar and easily recognised signs of albuminuric retinitis. There remains as an additional reason for adopting this course the fact that even in women who either do not have, or who survive, the fits, the kidneys do not always recover from the disturbance to which they have been subjected, and the patient not unfrequently remains the victim of chronic Bright's disease. On these grounds, therefore, severe albuminuria ought to be added to the list of indications for the induction of premature labour without waiting for the supervention of eclamptic convulsions before coming to a decision. This is not a specialists' question. It is one which any practitioner may be called upon to consider at any moment, and it is to be hoped in the best interests of his patient that he will henceforth recognise the extreme and manifold gravity of the risks attending the continuance of albuminuria in pregnant women.

◆

THE AFTER-HEALTH OF ATHLETES.

The death of the Dean of Ely last week recalls the circumstances in connection with the prominent part which this divine played in the promotion of the healthful pastime of rowing at the Universities of Oxford and Cambridge. It is not generally known that Dean Merivale was the first to suggest the inter-University aquatic contest which has since become so popular a feature among the annual athletic appointments. So long ago, however, as 1829 the late Dean took part in an inter-University boat race on the Thames, and the interest associated with such a fact at the present moment is that, despite his arduous career as an athlete, the advanced age at which he died was proof that his athleticism could not have done him any harm. Writing upon this subject in the year 1869, he said: "In my time we rowed almost continually from October to June, and there was no attempt at scientific training for special exertion of a few weeks or days. My own college boat's crew were generally reading men, and disposed to temperate and regular living. We abstained pretty constantly from spirits, smoking, and dyspeptic food, and were, I believe, all naturally strong of constitution. On the whole, I should say from my own observation of Cambridge rowing forty years ago that it was a thoroughly good and healthy exercise for the healthy and the temperate." These remarks are especially noteworthy as showing the kind of preparation which in those days was thought requisite for great contests. Now-a-days, of course, training is not only considered absolutely necessary, but it is carried to a degree which sometimes is undoubtedly excessive. Over-training is the bugbear which has to be guarded against, and unless steps are taken to check its occurrence there is certainty of harm resulting. The late Mr. Wilkie Collins was one of those who peremptorily held to the opinion that the athleticism of the age was becoming overdone, and was causing many evil effects from the excessive training to which it led. With a view to drawing public attention to his convictions on this matter he wrote a novel, one of his best, called "Man and Wife," in which the hero is depicted as a complete athletic failure in consequence of having been over-trained. There is no doubt that this subject of anti-athleticism was a pronounced fad of the great novelist in the same way as we have faddists of the virulent "anti" type in the present day. The late Mr. Skey again was an ardent opponent of modern athletics, and his efforts were equally as great as those of Mr. Wilkie Collins to prove his convictions in this respect. Happily, however, nothing has been proved against the ordeal of physical effort comprised in the inter-University boat race. No evidence has been forthcoming to show that the crews taking part in the contest have suffered in health in consequence of their exertions. In this connection, of course, it should be borne in mind that the crews are made up of specially picked men, those, indeed, who might be regarded as the "flower" of the undergraduate community, and this being the case, there is no difficulty in understanding how it is that they are able to take part in the annual inter-University boat race and successfully pass through the ordeal without either immediately or remotely being any the worse. Dean Merivale's statements respecting the healthiness of rowing as a pastime are as true now as when they were uttered more than twenty years ago. The one difficulty associated with the preliminary stage of such contests, namely, over-training, is carefully guarded against, both in the interests of the men concerned as well as in those of the University which was striving for the supremacy. Dean Merivale was himself a conspicuous example of the harmlessness of arduous athletic training upon a vigorous constitution, and his long and useful life was a sound argument against the theories advanced by those pessimists who have attempted to prove that athleticism was a thing to be condemned.

THE DETERIORATING EFFECTS OF FOG ON ANIMALS AND PLANTS.

The ever-increasing activity of manufactories, together with the rapid growth so manifest in town populations, brings prominently into notice one or two facts of considerable importance, although very liable to be overlooked in connection with the maintenance of health, whether of human beings, animals or plants. We are too prone to show a disregard of the deleterious nature of the gases constantly passed into the atmosphere through the various chimneys of the numerous manufactories, and the enormous quantities of carbonaceous particles from the thousands of houses annually added to, and which thus increase the evils from which all growing cities suffer. It is almost needless to repeat the fact that smoke is the chief element concerned in the formation of fogs, the denser kinds of which are a complete barrier to the radiation of light and heat. The act of breathing becomes difficult during foggy weather by reason of an increase in the carbonic acid gas, and a decrease in the due proportion of oxygen necessary to insure health and life. These atmospheric conditions when combined with a low temperature must be regarded as an important factor in the augmented death-rate of towns. Quite recently the deteriorating effects of fog on cultivated plant life has been made the subject of careful observation by Professor Oliver, who, by exposure of plants to fogs, has been enabled to furnish some new facts and salient features of the injuries caused thereby. We may premise our observations by saying that country mists uncontaminated by smoke cause no injury, and sea fogs are also stated to be quite innocuous to either plants or animals. Urban fogs, however, cause either local discolouration of the leaves without apparently affecting functional activity, or, as in some cases, the leaves fall off, and then show a more marked loss of colour. Cases of injury in the first group are clearly due to the greater or less quantity of an acid, probably sulphuric acid, since this is deposited in appreciable quantities on the leaves of stove plants. The chief of the changes, and which lead more directly to the speedy decay with change of colour in leaves, are said to be due in some measure to attacks by other chemical substances found in fogs upon their unprotected delicate internal tissues. The fog effects an entry into the cellular spaces by way of the stomata, and by its circulation brings the poisonous substances into immediate contact with the cell membrane of the living tissue. The cellulose offers but little resistance, the protoplasm is directly attacked and the starch withdrawn from the tissues. The chlorophyll, although in some cases its colour is not lost, finally undergoes decomposition. There appears to be some neutralising agent present in chlorophyll which retards the process of decomposition. With regard to the flowers, these are the first portion of the plant to exhibit the effects of fog, with the exception of bulbous roots, all of which are very hardy and escape with little or no injury. The loss of light caused by fog is a further and serious source of mischief, as in this way the assimilation of carbonic acid is much reduced, and the rate of starch production in the chlorophyll corpuscles is very small, and transpiration shows a marked diminution, and though absorption by the roots goes on, the cells become abnormally distended with water. Lastly, respiration is interfered with, the access of oxygen from without being a matter of increasing difficulty to the circulation owing to the faulty state of the circulation in the intercellular passages and the stoppage of the supply normally liberated during carbon assimilation. Deficiency of respiration naturally results in incomplete oxidation of many substances, particularly of the organic acids secreted by the plant, consequently under the conditions referred to the normal balance of power is gradually diminished, and the plant protoplasm is unable to offer resistance to the action of the poisonous impurities contained in the fog of towns. From a perfect knowledge of the action of fogs upon plants we may the better estimate their destructive effects upon human life, as exemplified in the recurring and increased death-rate usually published at this period of the year when fogs mostly prevail. It is hardly necessary, therefore, to point out that the knowledge gained by the scientific experimental study of the deteriorating effect of fog upon plants, conducted by the foremost botanist of the day, cannot but prove of the highest interest and value to the profession.

Notes on Current Topics.

Surgical Pitfalls—Drunk or Dying?

Two of the Dublin hospitals have been in serious trouble over the death of a woman upon whom an inquest has been held. She was found by a constable in the hall of her own house in an unconscious condition. She was taken to Sir Patrick Dun's Hospital, where she was examined by the house surgeon, Mr. Kiddle, and shown by him to Mr. Brooks, one of the surgeons who happened to be there. The surgeon, it appears, said to the house surgeon, "Oh, I think she will be all right," which the latter seems to have interpreted as meaning that the case need not be admitted to hospital, and the patient was therefore sent away. She was next taken to Mercer's Hospital, where, as stated at the inquest, the house surgeon, Mr. Elliott, declined to admit her, as to do so would be "against medical etiquette," and she was then taken back to her own house, where she remained in the same condition until morning. She was then taken to Jervis Street Hospital, where she was at once admitted, and died in a few hours, suffering, as afterwards appeared, from serious head injuries. Naturally these events gave rise to animadversions in the newspapers upon the management of the hospitals, and investigation meetings of the Governors of both hospitals were held. Those of Sir Patrick Dun's arrived at a verdict which declares the house surgeon free from blame, and attributed the non-admission of the patient to a misunderstanding by him of the remark addressed to him by Mr. Brooks. The Governors of Mercer's Hospital, on the other hand, hastened to pass a resolution which declares that no consideration of "medical etiquette" should prevent the admission of a patient whose condition renders admission necessary. The case for the house surgeon Mr. Elliott has, however, not yet been heard at all, inasmuch as he has been confined to bed with severe influenza. We shall, however, be quite prepared to hear from him that he never made use of any such observation about medical etiquette, and did not exclude the patient for any such reason. Speaking generally for hospitals and for the profession, we desire to say that it is and ought to be a universal rule in hospitals that in every case in which doubt exists as to whether a patient is suffering from brain injury or merely very drunk, the benefit of the doubt should be given to the patient and the case should be admitted. It is scarcely possible to go beyond this in hospital management, for if every patient with a cut head and in a semi-conscious condition were to be admitted to hospital (especially about Christmas time) each institution would require an observation ward as big as a concert room, a corps of resident police, and a substantial addition to its funds. Furthermore, it should be recollected that one of the cruxes of surgical diagnoses, even under the most favourable circumstances, is the differentiation of brain injury from excessive drunkenness. Almost all such patients present signs of head injury, and almost all smell strongly of whisky, and the surgeon would be remarkably acute who could pronounce, under the adverse circumstances of a midnight diagnosis, without the risk of occasional error. As to "medical etiquette" as a factor in the case, the public ought to be assured, as we can assure them, that in Dublin there is no such determining consideration, and we do not believe that the house surgeon of Mercer's ever gave such excuse for the non-admission of the patient. The fact that a patient had been considered by another hospital not to require admission might doubtless bias the mind of a surgeon in deciding about the admission of such a case, but "medical etiquette" has and ought to have no bearing on the matter.

The Notification of Tuberculosis in New York.

Notification of tuberculosis has been recommended in New York as the result of a commission of inquiry into the infectivity of the disease, and the Board of Health has adopted the following suggestion, viz., that a circular be prepared for distribution setting forth the danger of contagion from tuberculosis; that medical men be required to report all cases of tuberculosis within seven days of the time when such sick persons come under observation; that the medical sanitary inspectors should, as part of their duty, investigate cases of the disease reported, and take specimens of sputa for diagnostic purposes, as is done in cases of diphtheria. The Board also resolved to urge upon the hospital authorities of the City of New York the importance of separation, so far as possible, in the hospitals of the city, of persons suffering from pulmonary tuberculosis from those affected with other diseases, and that proper wards be set apart for the exclusive treatment of this disease. Elaborate instructions were also drawn up for the guidance of the sanitary inspectors with a view to the thorough disinfection of all places where evidence of infection existed. It will be interesting to learn whether, in the Report about to be issued by the Royal Commission on Tuberculosis, any reference has been made to preventive measures against the dissemination of the disease such as the Board of Health at New York has deemed to be necessary.

For Valour.

The act of bravery in respect of which Her Majesty the Queen has been pleased to confer the much-coveted Victoria Cross, upon Surgeon-Major Owen E. P. Lloyd was one which in the highest sense was worthy of the honour. During an attack upon the Sinia Fort by Kachins on the 6th January last year, Surgeon-Major Lloyd heard that his Commanding Officer, Captain Morton, who had left the fort to visit a picket about eighty yards distant, was wounded. He at once ran out to the wounded man under a close and heavy fire, accompanied by a native officer. On reaching Captain Morton, Surgeon-Major Lloyd despatched the native officer for assistance, and remained with his patient until assistance arrived; by the help of seven men the wounded officer was carried back to the fort, where he died a few minutes afterwards. The enemy were within ten or fifteen paces, keeping up a heavy fire all the time that Surgeon-Major Lloyd and his men were attending to Captain Morton, and four men were killed round him. The distinction is all the more welcome just now, when the conspicuous absence of the medical profession from any recognition in the New Year's Honours List is attracting general attention. Surgeon-Major Lloyd is an *alumnus* of Edinburgh, having taken the Licentiateship of the Royal College of Physicians and Royal College of Surgeons of that city in 1877. To this gallant officer and *confrère* we offer our heartiest congratulations in consideration of the great distinction which he has just received. There are now fourteen officers of the Government Medical Service upon whom the Victoria Cross has been conferred.

An Army Surgeon Killed in a Duel.

That most fatuous of all procedures for settling alleged or real insults, namely a duel, is happily not permitted by the beneficent laws of this country, and it is difficult to comprehend why the same excellent prohibition should not be in force among all civilised nations. In consequence of the fact that such encounters are allowed in Austria an army surgeon has just lost his life. At Innspruck quite recently a duel with pistols took place between this surgeon and a lieutenant. The former was shot in the lower jaw; the ball traversed the tissues of the neck, and death occurred within an hour of the receipt of the injury. The cause of the duel arose out of a quarrel excited by some hasty expression.

The Increase of Insanity among Negroes.

Insanity, according to Dr. H. J. Berkley, is vastly more frequent than formerly among the coloured races as a unit in the United States. The Report of the Lunacy Commission for the State of Maryland for the year 1892 gives a total of 278 negroes in institutions scattered throughout the State—130 males and 148 females. The census for the same year gave a total negro population of 215,897, or 105,886 black males and 110,011 black females. The proportion, therefore, of coloured insane to the entire coloured population would be about 1 to 814 males and 1 to about 747 females, or about 1 to 776 for the entire coloured population, which is considerably less numerically than the proportion of white insane to the entire white population, which stands somewhere in a ratio of about 1 to 525. The increase in insanity among the black races is attributed almost entirely to their altered social relations, the struggle for existence, which did not exist under the conditions of former slavery, and their more active competition with the white man, not only from an educational standpoint, but also in the various occupations for an every-day livelihood. There are other influences, also, which act deleteriously upon the negro in this respect, namely, his improvidence, his more constant debauchery, and the unhygienic surroundings in which he commonly lives. Dr. Berkley has met with nearly every form of insanity that is presented in the white races reproduced in the black; for instance, all forms of mania and melancholia are common, and epileptic insanity is frequent, and general paralysis is by no means so infrequent as is generally supposed.

The Forthcoming International Congress of Hygiene and Demography.

THE Secretary-General of the forthcoming Eighth International Congress of Hygiene and Demography, to be held at Budapest in the first week of September, has issued the provisional programme of the sections in Hygiene. The sections are nineteen in number, and are devoted to subjects of the most diverse description. The three first are, "The Etiology of Infectious Diseases (Bacteriology)," "The Prophylaxis of Epidemics," "The Hygiene of the Tropics"—each of which is fully provided with many suggested topics for discussion. Among other sections are "The Hygiene of Public Buildings," "The Hygiene of Communication (Railroads and Navigation)," and "The Hygiene of Sport." The first question which appears on the list of the latter section is, "The different kinds of travelling and their influence upon the nerves, the digestion, and the formation of blood. *Wedding Tours.*" The italics are ours. That such a subject as "wedding tours" should have been included among the topics suitable for discussion at a hygienic meeting seems somewhat puzzling. It would rather appear as if some wag of a translator had added "wedding tours" as a corollary to the main subject respecting which information was invited. Perhaps, however, he wishes it to be understood that a paper "On Wedding Tours, their influence upon the nerves, the digestion, and the formation of blood," would, if forthcoming, be particularly entertaining.

The Memorial Portrait of Mr. Colles, of Dublin.

MR. OSBORNE, the distinguished artist who was entrusted by the Memorial Committee with the painting of the portrait of Mr. William Colles, the veteran Secretary of the Royal College of Surgeons in Ireland, has completed his work greatly to his credit. It is a most admirable likeness, and the pose and facial expression are perfectly characteristic of the original. It will be hung, we expect, in a position of honour in the College of Surgeons, where it will perpetuate at the same time the cherished memory of Mr. Colles and the skill and judgment of the artist. The Memorial Committee is about to close the subscription in order that the artist may be paid for his work, and it is requested that those who have promised subscriptions will send them in, and those who have not already responded to the circular of the Committee will mark their respect for the deceased by entering their names on the subscription list. Mr. Colles was the Surgical Father of Steevens's Hospital, and the teacher of many scores of practitioners who got their education within its walls, and we are certain that if any have not subscribed to perpetuate his personality, it cannot be because they have failed to appreciate his long services to them and to surgery in Ireland.

The Medical Service on Board Emigrant Ships.

THE Report of the Committee of the American Public Health Association "On Sanitary and Medical Service on Board Emigrant Ships," recently issued at Chicago, contains some useful recommendations. Among other things it says that there should be one duly qualified medical officer to every two hundred and fifty passengers, and that the senior medical officer of every vessel should be required to keep—(1) A list of sick, recording in a book, in the order of their admission, the name, age, sex, birthplace, date of admission to treatment, date of death or discharge from treatment, disease, and such remarks as may be necessary to enable the inspecting medical officer at the port of arrival to have a clear and complete understanding of the case. (2) It is also recommended that he should keep a medical journal, in which each medical officer, when there are more than one, should record the medical history, including the symptoms and treatment, of every case, to be approved and signed by the senior medical officer at the close of the day's record, and that such list and medical journal should be submitted to the health authorities of the port of arrival, and the accuracy of the statements in such records should be established by oath, and penalties for perjury provided. These recommendations appear to have much in their favour, especially the first, which limits the number of emigrants to the care of one surgeon. Usually on board emigrant ships, no matter how many emigrants may be present, one surgeon per ship is deemed to be sufficient. Obviously economy is the only point aimed at by the shipping companies.

The Law relating to Police-Court Fees for Medical Witnesses.

IT is very necessary that all medical men should become conversant with the laws affecting their interests when they are summoned as, or have to act in the capacity of, medical witnesses. This is a detail in professional life which should never be overlooked, and more especially so, because of the fact that the laws in question are very explicit, and are in no sense ambiguous. Strictly speaking, our remarks should apply chiefly to young medical men, those, for instance, who are holding appointments as house surgeons, or as resident medical officers at hospitals, for experience shows that when mistakes occur in the interpretation of these laws, it is usually our younger *confrères* who have not quite made themselves acquainted with the precise details of the special clauses in the Acts. We have been led to refer to this subject on account of some remarks which fell last week from the Liverpool stipendiary regarding the refusal of a resident medical officer at the East Dispensary to give a certificate as to the nature of a wound on a patient's arm, unless he was summoned to attend court and had received a fee of half a guinea. The stipendiary observed that if this attitude was assumed by the medical men in his district he would take care that they were summoned as seldom as possible. If they were subpœnaed and had their travelling expenses paid they could claim no fee, and if they would not attend under these circumstances he would have to issue a warrant. Complaint was also made by the police in another case in which one of the resident medical officers at the Liverpool Royal Infirmary refused to give any information in a case of criminal assault until he appeared in the witness-box. In reflecting upon both these cases it appears to us that there was no wilful intent to adopt a hostile attitude against the police authorities, but that the cause of the magistrate's strictures arose merely from a mistaken idea of the existing law on the subject by the young medical men concerned. The law very explicitly states that in cases of summary convictions, the making or not making of an order for costs is in the discretion of the magistrates, and the Secretary of State cannot interfere with them. The other class of cases, of course, in which medical witnesses have to attend police-courts, and the prisoners are sent for trial to the assizes, fees for attendance are always paid. Possibly the mistake arising from the confusion of these two capacities in which the services of medical witnesses are concerned was instrumental in leading to the *contretemps* which occurred last week at Liverpool between the resident medical officers at the hospitals and the stipendiary.

Inquests at Dartmoor.

A JURYMAN who served on an inquest lately on the body of a convict who died in Dartmoor Prison has written a forcible letter to the *Western Morning News*. He makes allegations that require immediate official investigation. In this particular case the deceased said he was unable to work. During November, however, he was punished seven times for refusing to work, his punishment consisting of three days' separate cells, bread and water, and loss of marks. At the end of the month he was ordered out to heavy work, after three days' punishment, and it is said he had to be assisted to the scene of labour. The juryman proceeds: "He then told the warder he could not work, and was (as is usual) handcuffed with his hands behind his back, and had to remain there until the afternoon work was over. Next morning he was found dead in his cell." This case, if the facts are even remotely true, points to a lax medical supervision. It may be true that the inmates of a convict prison are likely to comprise many cunning and confirmed malingerers: at the same time, however, a careful examination could leave little doubt as to the real nature of any alleged illness. In those cases where such a doubt existed it would be better to keep the convict under observation for a few days rather than risk his life by sending him out to heavy work. At the above-mentioned inquest the coroner concurred in the suggestion that in all cases of sudden death among the convicts an outside medical man should be called in. Some such safeguard is obviously needed, as the fact of a death occurring from the imposition of improper punishment and work would in itself render the medical officer, under whose sanction these things are done, an improper witness at any subsequent inquest.

A Proposed Memorial to Sir Andrew Clark.

MUCH can be said in favour of the proposal to institute some memorial of the late Sir Andrew Clark by the Fellows of the Royal College of Physicians, London. Sir Andrew's reign at the College was a conspicuous one in every way, and is worthily deserving of some permanent and tangible recognition. No details have as yet been decided in respect to the form which the memorial should take, but whatever the ultimate decision may be, it is certain to commend itself to the Fellows and to meet with general support. Of lectures, there are enough and to spare at the College, associated with great names, although undeniably a fitting way of perpetuating Sir Andrew's memory would be by the foundation of a "Clark Lecture," with some pulmonary disease for its subject. The simplest method, of course, would be to place a bust of Sir Andrew in the College: but does not the eventful and successful occupancy of the Presidential Chair by the late President call for some less conventional method than this of perpetuating his memory?

The Harness Prosecution.

THE Harness prosecution continues to drag its weary way along. Once a week is considered often enough for the case to be heard, and the end still seems to be far distant, in view of the large number of witnesses who have yet to be examined. The most amusing incident at the last hearing was the intimation by Mr. Avory, the counsel who appeared for Harness, that the latter was anxious that the magistrate should inspect the premises of the Medical Battery Company in Oxford Street and see the manner in which they were fitted. Mr. Hannay, however, declined, and naturally so. Laconically he said he did not think there was anything which he wished to see there—at present.

Fires in London Hospitals.

A SERIOUS fire occurred early in the morning of the 4th inst. at the Royal Victoria Hospital, in the East-end of London. It broke out in the top storey, but after doing considerable damage, was got under, fortunately without injury to patients, of whom there were 160 in the building. The outbreak, the origin of which is unknown, was confined to the top floor, from which about 60 men had to be removed. We learn from members of the medical staff that none of the patients received injury, either from the shock or the removal. The official Fire Brigade report states that about 80 feet of roof of main building have been destroyed, and the dormitory on the third floor, about 30 feet by 25 feet, burnt out with its contents. The rest of the building is seriously damaged by fire, smoke, and water. Nothing but the very prompt action of the Fire Brigade prevented a most startling catastrophe. It will be interesting to know what appliances for extinguishing fire existed in the hospital. Following on so closely the fire at Guy's Hospital in Christmas week, which fortunately was got under before much damage was done, the question naturally recurs as to the sufficiency or suitability of appliances in our hospitals for coping with these sudden outbreaks to which, of course, all are liable. In matters of this kind the tendency is to wait until public attention is aroused by some great catastrophe such as happened at an American institution last year.

Important Researches into the Purity of Aerated Waters.

THE researches of Dr. Hankin into the microbic qualities of aërated waters, conducted recently at the Government Laboratory, at Agra, are interesting from several points of view, as well as being reassuring. Among other things he has definitely determined by experimentation that the gas in the aërated waters acts as a poison to the microbes, so much so, that a bottle of soda water which was teeming with bacteria when first made, is generally found to be perfectly free from the micro-organisms at the end of a week. This is, of course, a great discovery to have made, and those who resort largely to these waters in their beverages will undeniably duly appreciate it. It is, moreover, most satisfactory to note that the cholera microbe appears to be the easiest to kill. It generally succumbs within an hour or two of bottling. On the other hand, the typhoid bacillus seems to be the most resistant to the action of carbonic acid gas. In one case the microbe was found to be still active at the end of a week, while in another instance it succumbed within five days, in ordinary soda water. The only drawback to these observations is that the experiments were conducted with soda water manufactured in India, where, owing to the high temperature, bottling has to take place at a much higher pressure than is the case in England. Dr. Hankin, therefore, is obliged to admit, basing his conclusions upon certain observations of Mr. Slater, that carbonic acid gas at a relatively low pressure in English soda water is a less powerful germicide than that present in Indian soda water. Nevertheless, however this may be, it would appear that nearly all risk from infection from drinking foul soda water can be avoided by keeping it a week or more before use. The point is one of so much importance that artificial mineral water manufacturers might bear it in mind, and only issue their goods to customers after the specified time has elapsed.

Congenital Sterility in a Woman.

STERILITY is but seldom the result of congenital causes, but a curious case which is recorded in the current number of the *Indian Medical Gazette* shows how Nature may forget herself, and how much may be at fault without any suspicion existing of the extent of the congenital deficiency which may be present. A Hindu female, aged about twenty, was brought by her husband to an out-door dispensary. She was married when she was twelve years old. She was small in stature and dwarfish; her general health was good. She had never menstruated, or been pregnant, the mammary glands were rudimentary. The sexual act had presented no difficulties. On examination there was no hair on the pubis or in the axillæ. The vagina, was found quite capacious, but there was complete absence of the uterus and ovaries. By means of the bimanual examination this fact was clearly demonstrated.

Vacant Medical Officerships.

THE retirement of Dr. Stevenson creates a vacancy in the post of Medical Officer of Health for Paddington. The Medical Officership at Liverpool, so it is announced, will be shortly vacant. There is likely to be keen competition for this appointment, as it is one of the best paid of its kind in England, namely, £1,000 per annum. One other post, that of Medical Officer to the County Council, commands a similar sum, while the City of London pays £1,200 to Dr. Sedgwick Saunders. Turning to another branch of the Civil Medical Service, we understand that one of the important Commissionerships of Lunacy will soon be vacant.

A CONGREGATIONAL Minister named T. G. Vince was fined five shillings and costs at the Birmingham Petty Sessions last week for refusing to have his child vaccinated. The defence was conscientious objections to vaccination, and the defendant further added that "he really could not comply with the law." All anti-vaccinators desirous of studying economy must be finding their obstinacy now rather troublesome.

THE Government of India has promised to provide the services of a qualified medical officer to superintend the Pasteur Institute in India, as soon as the scheme is fully matured. This concession will be equivalent to an annual contribution of Rs.12,000; other subscriptions for the scheme are being freely promised.

A FEW years ago it was calculated by the late Sir Francis Bolton that the sewage of upwards of 70,000 people was delivered direct into the Thames or its tributaries above the intakes of the metropolitan water companies.

IT is not generally known that there are two London Medical Societies, but such is the fact. There is one "London Medical Society" of London, England, and there is another "London Medical Society" of London, Ontario, Canada. The names are the same, but the societies are far enough apart to prevent confusion arising therefrom.

MR. W. F. FULHAM, of Balbriggan, has sustained a compound fracture of the right leg in consequence of having been thrown from his trap. He is making satisfactory progress, Mr. Nolan and Mr. McArdle being in attendance. The horse which Mr. Fulham was driving shied, and the trap was upset.

THE well-known firm of Messrs. Allen and Hanburys has been converted into a limited liability company. All the shares saving a few issued have been taken up by the present partners, who remain as managing directors.

There was a large and distinguished attendance at the funeral of the late Professor Robert Bentley, which took place last week at Kensal Green. The deceased was Professor of Botany at King's College, and was also editor of the *Pharmaceutical Journal.*

At the Birmingham Police Court last week fines of £15 and costs, and £5 and costs, were respectively inflicted upon butchers for exposing tuberculous beef for sale.

The Manchester City Council last week confirmed, after a long discussion, the recommendation of the Health Committee fixing the salary of the new Medical Officer of Health at £850 per annum.

Mr. Richard Cronin, of Slane, has been placed on the Commission of the Peace for the County of Meath by the Lord Chancellor, on the nomination of the Marquis of Headfort.

A nurse named Helen Caddick, æt. 31, died at the Queen's Hospital, Birmingham, last week, of typhoid fever. She had just completed her training.

◆

Scotland.

[From our own Correspondents.]

Leith and Compulsory Notification.—After a long period of indecision it seems that the Leith Town Council are going to adopt the Compulsory Notification of Infectious Diseases Act after all. When the proposal came last before them they refused to do so until they had a proper fever hospital in which to place the notified cases. They were urged to this course by their Medical Officer of Health. Now, however, owing to the pleasing uncertainty as to the number of small-pox cases in the town, and to the consequent feeling of insecurity among the inhabitants, the principal opponents of the Act in former days have apparently reconsidered their decision, and wish to adopt its provisions as soon as possible. A motion to this effect will come before the Council shortly, the proposed date of the innovation being on or after the 15th of March.

Alcoholic Excess on New Year's Day.—It is an unfortunate fact that on the first day of each year an enormous quantity of alcohol is consumed by many of the inhabitants of the Scottish cities and towns. The magistrates have for a few years back endeavoured to keep this excess down to a lower level by recommending all public-house proprietors to close their premises for the day. This recommendation is in reality a command, for they promise to remember those that do not close on next licensing day. The result has been satisfactory, for, although the number of police cases shows only a slight diminution, the number of serious cases treated at the hospitals has fallen to almost *nil*. In the Edinburgh Infirmary, for instance, a very considerable number of cut heads were dressed, and one or two more serious cases of injury admitted, but there was an almost total absence of those cases of acute alcoholic poisoning which used to be so numerous five or six years ago. It is highly improbable that less alcohol, in the aggregate, is drunk, but being spread over one or two days the excess taken does not prove so hurtful.

Dundee and Dr. Tyson's Cure for Drunkenness.—During last week sixteen persons were put under Dr. Tyson's "cure" for drunkenness in Dundee. Arrangements were made by a number of persons interested in temperance work in the city, and a Mr. Stephen, a chemist in London, was brought down to help. It appears that Mr. Stephen's firm have taken up the cure. Ex-Lord Provost Hunter, who presided, said that he looked on the scheme with suspicion, that Tyson's agent in Australia had been fined 10 guineas for selling the medicine without labelling it poison, and that the commercial value of the drug sold for 10 guineas amounted only to 2s. After some explanations by Mr. Stephen the Chairman left the meeting. Bailie Smith took his place, and elicited from Mr. Stephen that Dr. Tyson is not a teetotaller, and that the doctor had made a considerable sum of money from the cure. The subsequent proceedings should prove interesting, and we trust that those well-meaning folk who are thus experimenting will not lose very many guineas for that which is worth only 1-150th of the sum paid, without benefitting drunken humanity.

The Professorial Chair of Midwifery in Glasgow.—Since the resignation of Dr. Leishman as Regius Professor of Midwifery in the University of Glasgow, a good many names have been put forward as likely successors to the chair so long and honourably filled by that gentleman, and the delay in filling it has led to no little inconvenience and anxiety. The matter, however, has now been set at rest by the appointment by the Crown, on the recommendation of the Secretary of State for Scotland, of Dr. Murdoch Cameron, who has for some time past occupied the position of Assistant Professor of Midwifery in the University and Lecturer on Obstetrics in Queen Margaret's College. We congratulate Dr. Cameron on his appointment.

◆

MEDICAL SOCIETY OF LONDON.

Last Monday's meeting (Jan. 8) opened with a paper by Mr. William Anderson on a very interesting and somewhat puzzling case. It was that of a lad, æt. 15, who, after a day's skating, returned home very much done up. A day or two later he developed swelling of and pain in the joints of the lower limbs, with a high temperature and abundant sweats. His medical attendant not unnaturally diagnosed rheumatic fever. The constitutional disturbance did not subside for ten weeks, when it was discovered that all the joints of the lower limbs were fixed and rigid. In endeavouring to procure some mobility of the knee the stretched and inelastic skin broke down, leaving a very nasty wound. Later an abscess formed in the neighbourhood of the hip, and this was followed by atrophic lesions affecting the skin and certain groups of muscles in the lower limbs. Ultimately the lad was taken to St. Thomas's Hospital, where he was put under a course of massage. In the course of some months he recovered so far as to be able to get about by the aid of a stick. He was shown at the meeting to illustrate what is now described as "A Case of Peripheral Neuritis followed by Multiple Ankylosis and Atrophic Manifestations."

Dr. Pasteur alluded to a case brought by him before the Clinical Society in 1889 which resembled this case only, so to speak, in differing from it in every essential feature. The onset in his case was gradual instead of acute, all the joints of all four limbs were involved as well as those of the jaw, and no improvement had followed any plan of treatment, the deformity, which was not very marked in the author's case, being very conspicuous in his own case as he proved by handing round photographs of the patient. On the whole, he concluded that his case belonged to quite a different category to that of the author.

Mr. Lockwood thought the symptoms were compatible with the disease having been due to some infective agent, and he experienced a difficulty in thinking that any other cause would account for such extensive suppuration as this lad had undergone. The existence of peripheral neuritis was not inconsistent with this view, as he pointed out, because peripheral neuritis occurs in association with various forms of septic infection. He asked whether there had been any effusion into the joints, and also whether any albumen had been discovered in the urine, pointing out that such was usually the case in septic infection.

Mr. Richards ventured to suggest influenza as a possible explanation of the multiple lesions.

Mr. Anderson, in reply, explained how he had dismissed the possibility of the case being due to infection, insisting particularly on the fact that the abscess in the thigh did not come on until ten weeks after the onset of the symptoms, that the traumatic condition was limited to one side, and to the fact that the muscular and cutaneous lesions did not appear until after that date. There had been effusion into the joints at the beginning, but there was none on the lad's admission to the hospital. No albumen had ever been detected in the urine subsequent to his admission, and nothing was known of the condition previously in this respect.

THE THYROID TREATMENT IN VARIOUS SKIN DISEASES.

Dr. Phineas Abraham gave the results of some ninety cases of various skin diseases in which he had tried the effects of the administration of thyroid extract in the form of tabloids as prepared by Messrs. Burroughs, Wellcome, & Co. Of this number there were sixty-five cases of psoriasis, the remainder being made up of cases of lichen planus, lupus, leprosy, eczema, &c. Unfortunately the value of his results is seriously impaired by the fact that in most of the cases the patients were making use of some other treatment at the same time, but Dr. Abraham arrived at the following conclusions: (1) that the ingestion of thyroid extract has no constant effect in psoriasis and other skin affections; (2) that the results are often negative, and in a few instances the disease is even aggravated; (3) that in a small number a markedly curative effect was produced; (4) that there are no indications of the class of cases likely to be benefited thereby; (5) that severe constitutional effects are often produced; (6) that age and sex do not influence the effects of treatment, successful or otherwise.

Dr. Morgan Dockrell pointed out that seborrhœal dermatitis is often mistaken for psoriasis, adding that the constitutional effects were often very marked, the beneficial effects being most frequently observed in the young and in the debilitated.

Mr. W. Anderson referred to a typical and severe case of eczema in a man, æt. 35, of thirty years' standing, in which not only did no good result follow, but his last condition was worse than the first, though when the external application of tarry preparations was substituted the patient promptly and rapidly improved.

Dr. Hingston Fox pointed out that the gland itself varies considerably, not only in size, but probably also in physiological activity. Moreover, the gland undergoes periodical changes in woman, and probably also in animals, and as we know nothing of such changes, there is a wide margin for discrepancies of observation. Lastly, he observed that, until chemists have succeeded in isolating and defining the active principle of thyroid gland, no hope could be entertained of obtaining anything like uniformity of results.

Dr. Abraham, in reply, admitted the possibility, or rather the probability, of such variations in strength, but pointed out that at present one had to do the best one could with the material at one's disposal. He claimed to be able to distinguish between seborrhœal eczema and psoriasis, and added that though his results would doubtless have been more valuable had other methods of treatment been discarded while experimenting with the thyroid extract, this was not always possible when dealing with out-patients who have opinions of their own as to the treatment to be followed.

Special Articles.

COMPULSORY NOTIFICATION IN ENGLAND AND WALES.

UNDER the above heading, a "Special Report, presented to the Parliamentary Bills Committee of the British Medical Association, by Mr. Ernest Hart, Chairman of the Committee," has for three weeks occupied the columns of the *British Medical Journal*, taking up in all seventeen pages. It is not very difficult to discover the motive with which the Report was drawn up, namely, if possible to provide cogent arguments for those who are desirous of persuading Parliament to make notification compulsory throughout the country. In a footnote, on the first page, appears the following: "We would, in this connection, draw attention to the action of Mr. Alfred Thomas, in Committee of the House of Commons on the Local Government (England and Wales) Bill, in proposing the insertion of the following clause: 'As and from the appointed day, The Infectious Diseases (Notification) Act, 1889, and the Infectious Disease (Prevention) Act, 1890, shall come into operation and be compulsory in every part of England and Wales,'" &c. But it is of importance to note that the information afforded in Mr. Hart's Report is traceable in every instance to interested parties, namely, to Medical Officers of Health. Thus, Mr. Hart says, "The question how best to proceed with the greatest chance of success was decided by a resolve to group sanitary districts in geographical counties, treating such county as a unit, save as regards Wales, which it was held best to divide into two sections only, namely, North and South. To this end, *request was made by circular last April of the Medical Officers of Health* of the London districts and of the 1,101 provincial districts for a return of all notified cases and registered deaths from each notifiable disease during the twelve months ended *March 31st*, 1893, together with the cost of the certificates received in the same period." It is somewhat difficult, however, to understand a later sentence, "But for all practical purposes the returns may be read as having concern with the twelve months *January to December*, 1892," inasmuch as forms on the latter basis were only issued to those who had not complied with the initial request. We are informed that *only* 86 *per cent.* of the population under compulsion finds place in the returns. But considering the source of the information, we are not surprised to find Mr. Hart able to say, "And just here it may be well to declare that I have not received a single word against the principle involved in the Act. . . . On the other hand, many officers speak highly of the smooth working of the Act, and *the absence of all comment from the majority* *of districts* in itself speaks well for the system." At the same time, it is well to bear in mind that *silence* does *not* always *give consent*. If the Local Government Board desires the passing of a certain measure, woe betide the unlucky officer of health who hinders it!

The whole of Mr. Ernest Hart's Report is taken up with returns of cases, death-rates per case, and cost of notification, and we have no hesitation in saying that, except in regard to the last named, the whole thing is valueless, or next door to it. Instead of being founded on a rock, the vast edifice which Mr. Hart has raised rests on a veritable morass or quagmire, namely, the number of notified cases.

In the first place, it is unquestionable that a large percentage of notifiable cases are not notified, and in the second place there is reason to believe that a considerable proportion of those notified are non-infective, being, for reasons easily understood, wrongly diagnosed. It is illogical to assume that these balance each other, and that, therefore, the returns are practically correct. We have no reliable data upon which to base death-rates per case. The death-rates per 1,000 of the population are the only trustworthy ones, and it has been shown over and over again, in our columns and elsewhere, that the light thrown upon the question by these is adverse in the extreme to the system enforced by the Notification Act. Throughout the Kingdom that system has produced its baneful results, and England is now a greater sufferer from infective disease than for many years past. We confidently predict that in most respects the returns for 1893 will be even worse than those for 1892. In any case, it will be madness to proceed to further legislation in consequence of a Report concerning one year only.

HYSTERECTOMY BY THE CLAMP OPERATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The proposal contained in Mr. Taylor's paper, published in your current issue, is not new, but is essentially as proposed by an author (an Italian I think) some eight or ten years ago. I tried it and discarded it after one or two cases, for many reasons, which need not be gone into now, but for one which is good enough. This is that it is essential alike for the primary and for the secondary good results in clamp hysterectomy that the peritoneum should be closed accurately and at its own level. For this purpose the use of a suture below the clamp gives the greatest security, and to that simple proceeding I am satisfied that I owe much of my present low rate of mortality in clamp hysterectomy—less than 5 per cent. over the last four years. This further concerns the ultimate results of the operation, specially the production of hernial protrusion. As I have often pointed out, this evil result is due, more than to anything else, to the intervention of peritoneal elements between the structures divided in the abdominal wound. Anything which crumples up the peritoneum into the wound so as to prevent muscle coming into contact with muscle, and tendon with tendon, tends to the production of hernia. The edges of the peritoneum ought therefore to be included in the stitches with the narrowest possible margin in all cases; and in the case of the clamp stitch in hysterectomy the first inclusion ought to be peritoneum alone, to secure a perfect fit round the collar of the stump, the absence of the fatal triangular gap, and the prevention of peritoneal crumpling into the wound. The method which Mr. Taylor seems to believe to be new must secure the latter so effectively that at the end of the case the upturned peritoneum and the skin alone will form the covering of the stump, a condition which is certain to produce ultimate protrusion. Until I paid close attention to this point I was greatly disappointed with the frequent occurrence of this secondary complication of my results—now it is hardly known.

I am, Sir, yours, &c.,
Lawson Tait.

7 The Crescent, Birmingham.
January 4th, 1894.

"UNQUALIFIED MEDICAL MISSIONARIES."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Some letters have appeared animadverting, as I think, unfairly, not to say unkindly, on the Zenana Medical College for Women.

Will you kindly permit me as one of the oldest lecturers in the College to refer to them?

First, I should say with us it is a question of conscience. We do not profess to "qualify," but to make the lady missionaries as useful as possible, by giving them a sound medical training, as far as the time at their disposal and their pecuniary means will allow, and for countries where qualified *men* are not admitted to attend upon women, and where women may be qualified, and because not missionaries are not the lady helps required. Moreover, in the parts where our trained ladies go, to India, China, Africa, and Burmah, the natives care very little for qualified persons, and know little of, and care less for, Universities or Colleges of Physicians or Surgeons.

JUL 20 1894

It is urged that in two years our lady students cannot know much. Granted, but two years well employed will often do as much as three or four carelessly consumed; and, that it is so, every examiner knows, and the number of persons plucked every year proves.

In olden times, when young men served an apprenticeship, it was always noticed that those who had been assiduous apprentices almost always carried away the prizes. They were so well grounded before they came to college. Will anyone maintain that the training of girls in a college, where they are well taught, can be other than a great good to a missionary woman, though she is not fully qualified?

Again, the Church Missionary Society, and other missionary societies, take care to teach their pupils a little medicine and surgery, as well as cooking and carpentering, &c. It is not supposed that they are perfect in these departments; but can it be denied that the knowledge so acquired is of immense advantage to missionaries among ignorant heathen, or savages? The Zenana Medical College undertakes to give medical, surgical, midwifery, &c., &c., instruction in a systematic manner.

Again, it certainly would be an advantage if women could be trained for five years as medical women, but who is to find the women and the money? Few wealthy ladies follow missionary life. Those who adopt the medical profession, do as the great majority of medical men have done, as a *vocation* by which hereafter they shall be able to earn their living. If Miss Jex-Blake and her friends will provide the funds, doubtless more medical missionaries will be qualified. But personal poverty, and the want of funds for this purpose among many societies, preclude five years' maintenance and a five years' course of study in ordinary medical schools. More than this, I am informed that the authorities at medical schools, even those managed by lady doctors, actuated by the narrow-minded principle that *once* prevailed in the London University, do not allow women to attend special courses, unless attendance upon the complete course of study be given. If, as in the University of London, a woman might study anywhere without prejudice to some future exam., it might be different. Then why do not these discontented ladies seek to do away with this system of boycotting which is at best an illiberal monopoly? There is then no alternative. The well-founded knowledge of medicine, surgery, and midwifery, &c., obtained at the college is a great advantage to a lady missionary, *and the result has proved it*. Take the practice of midwifery. Even in England, up to the present day, and for years, no "qualification" for women was necessary, nor is it yet so. The Obstetrical Society has done its best in this direction, but the number they qualify is a drop in the ocean. In China, see the wonderful success of Miss Sugden (one of our two years' trained ladies), and that for years. There, if a patient cannot be delivered, they wait four days, and then the woman is left to die; or, if a limb of the child can be got hold of, it is pulled out piece by piece.

Then, consult those who have watched the progress of these ladies—where, assisted by qualified practitioners, *they have merited their entire approval*, as well as that of high Indian and other authorities.

It was Miss Sugden who, when all Europeans had to flee to the "men of war" for safety at Hangchow, alone ventured amid the excited mob who had sought to murder the missionaries, to her hospital to attend to the sick, and that mob, awed by her courage in facing danger, and touched by the recollection of what she had done for their wives and children, allowed her a free transit, the Governor himself sending a message to her that she would not be touched. Let me ask of what avail would any medical qualification have been here?

I deeply regret to see such perverse disputations going on against a measure which essentially is in the service of our Great Master and has helped very effectively the cause of Christianity.

I am, Sir, yours, &c.,
C. H. F. Routh, M.D. Lond.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I notice an article under the above title in your last issue with which my name is connected, and I hope that you will allow me to furnish an explanation with regard to it. By an oversight on my part you were not furnished with a statement concerning the founding of the "Livingstone College," instituted for the purpose of giving instruction in the *elements* of practical medicine and surgery to gentlemen proceeding as lay—not medical—missionaries into spheres where but little, if any, medical knowledge exists.

With you, Sir, I emphatically agree that every mission station should have a duly qualified medical practitioner, and deprecate any but such being styled "medical missionaries," and, in fact, all who enter for the course of Livingstone College are obliged to sign a declaration stating that they will not take to themselves "the title of medical missionary," nor assume the duties of a qualified medical man. But unfortunately, although there are nearly two hundred men and women in the mission field holding British qualifications, this does not in any adequate way meet the acknowledged need. It was, therefore, on behalf of the missionary himself and his fellow-missionaries, stationed often in very unhealthy districts, quite as much as for the natives around, that this attempt at simple instruction has been started.

I have not had the opportunity of seeing the article in the American contemporary you quote, but think that the scope of the work of the College must have been unduly magnified, and I am sure but few could object to give to missionaries such an amount of training as may enable them to meet the emergencies which must inevitably arise, and save lives and relieve suffering in the absence of qualified help.

In conclusion, I may add that we are receiving the co-operation of the staffs of the West Ham and Poplar Hospitals, besides occasional help from other teachers attached to various hospitals, as stated in the prospectus, and that the scheme was very favourably considered by the medical committee of one of the large medical schools in London, who had the plan of work put before them.

I am, Sir, yours, &c.,
Charles F. Harford-Battersby,
M.A., M.D. Cantab.

33 Mornington Road, Bow, E.
Jan. 5th, 1894.

[We cannot approve of this scheme for the reasons already given, and when we learn from the prospectus that these lay medical missionaries will be taught "the treatment of diseases of the eye," our opinion is further confirmed. No knowledge, save a dangerous knowledge, could be possibly acquired of this special branch of the profession under the circumstances in question, and we must repeat that this "Livingstone College" has been founded on wrong principles, and is calculated to do more harm than good.—Ed.]

◆

Medical News.

Conversazione of the Harveian Society of London.

The annual meeting and *conversazione* of the Harveian Society will be held on Thursday, the 18th inst., at 8 p.m., at the Stafford Rooms, Titchborne Street, Edgware Road, W. The President, Mr. Malcolm Morris, will deliver the Annual Address. It is proposed to hold an exhibition of the various methods by which disease may be depicted, comprising examples of photography, microphotography, drawing, painting, engraving on wood and stone, electrotyping, modelling and plaster casting. It is anticipated that a collection of these and other processes, many of which are but little known, will prove instructive and interesting. All members of the medical profession are cordially invited.

A New Inebriate Home

For men has been opened at Ranelagh Road, Ealing, by the London Diocesan Branch of the Church of England Temperance Society. The institution has been established to meet the wants of middle-class inebriates, who cannot afford to pay the fees asked by existing homes; and while the best medical attention will be given, recreation and occupation will form a part of the treatment. Patients are received at 31s. 6d. per week, and communications should be made to Rev. Dennis Hird.

Royal College of Surgeons of England.

The following candidates, having passed the necessary examinations, were at the December meeting of the Council admitted Fellows of the College:—

Thomson, St. Clair, M.D.Lond., M.R C.S.Lond, date of membership, Nov. 16th, 1881
Wilson, Thomas, M.D Lond., L.S.A., April 19th, 1883.
Kelson, William Henry, M.D.Lond, L.S.A., Jan. 30th, 1885.
Pollard, Charles, L.R.C.P.Lond, Jan. 22nd, 1886.
Roxburgh, Alex. B., M.B. and B.Ch.Oxon., Nov. 10th, 1887
Spurrell, Charles, L.R.C.P.Lond., Feb. 13th, 1890.
Yearsley, Percival Macleod, L.R.C.P.Lond., May 8th, 1890.
Ionides, Theodore H, M B Lond., L.R.C.P.Lond., Jan. 28th, 1890.
Jones, David John, L R.C.P.Lond., Nov, 13th, 1890.
Leedham-Green, Charles Albert, L.R.C.P.Lond., Feb. 12th, 1891.
Low, Vincent W., M.B.Lond., Feb. 12th, 1893.
Rochfort-Brown, H., L.R.C.P.Lond., Feb. 12th, 1891.

Six other gentlemen passed the examination, but, not having attained the age of twenty-five years, are not yet entitled to their diplomas as Fellows of the College. Twenty-one were referred back to their professional studies for six months, and one for twelve months.

The following gentleman, having previously passed the necessary examinations, and having now attained the legal age of twenty-five years, was also admitted a Fellow of the College:—

Salter, Charles Edward, L.R.C.P.Lond., Member July 30th, 1891.

The following gentleman, having previously passed the examinations, was admitted a Member of the College:—

Morris, Richard Brindley, L.S.A.Lond.

The following gentlemen, having passed the necessary examinations, were at the same meeting admitted Licentiates in Dental Surgery:—

Percy Arliss, Herbert Grimsdale Ashby, William Badgery, Francis Henry Boiley-King, W. Henry Griffiths Baker, Arthur Leigh Bostock, Edwin Bowden, Arthur Vidler Brimmer, Frank Charles Bromley, Leonard Brown, Robert John Bulgin, Joseph Henry Burroughs, Frank Holly Carpenter, Sidney Henry Mark Carpenter, Edward Clayton, Ernest Victor Coles, Ashley Bloomfield Densham, Walter Arnold Densham, David Dunlop, Albert John Gear Evans, John Robert Freeman, Wilfrid William Gabell, Charles Frederick Haines, John Trevor Hankey, Arthur William Henly, William Meredith Jones, Stephen Keele, Ernest Vincent Knight, Hugh Love, Walter John May, William Francis Mellersh, Lancelot Brainard Myers, John Brodribb Parfitt, Harold John Pickering, H. Burbery Rowe, Robert Satterthwaite, Arthur Newton Summerling, Frank Walker, Ferdinand Hammans Wallis, Richard Robert Ward, George William Watts, Gerald Bertram Webb, Rupert Wheatley, Geoffrey Whitworth, George Williams, Walter Robert Wood.

Seventeen candidates were referred back to their professional studies for six months.

◆

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this Journal, price, 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

TREATMENT OF PRURITUS VULVÆ.

W. P. M.—A possible cause of such obstinate pruritus vulvæ as that referred to by our correspondent might be the existence of diabetes. We would, therefore, suggest a careful examination of patient's urine with the view of ascertaining if any trace of sugar be present therein. Should this be the case salicylate of soda in fifteen grain doses every fourth or sixth hour may probably be found useful. Should the case, however, not be thus complicated with diabetes then we would suggest a further trial of such local applications as the oleat of chloral, or a saturated solution of boric acid, or a strong solution of iodoform in glycerine as advised by Dr Goodall of Philadelphia, or else the free employment of ordinary black wash from which we have obtained very satisfactory results in many cases of the kind referred to.

DR. R. R. is thanked for the newspaper cuttings, which he will find have been dealt with in another column.

CONJOINT EXAMINATIONS BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am desired by my Committee to draw the attention of those interested in medical education to the announcement in your advertising columns that the offices of these Conjoint Examinations will, after January 1st, 1894, be transferred to the Royal College of Physicians, Kildare Street, Dublin.

I am, Sir, yours, &c.,

Dublin, Dec., 1883. GREENWOOD PIM, Sec.

MR. D. C. (Glasgow).—Thanks for the offer, but the material will be more suitable for the lay press than for this journal.

Meetings of Societies, Lectures, &c.

WEDNESDAY, JANUARY 10TH.

THE SANITARY INSTITUTE.—At 8 p.m , R. Thorne-Thorne, C.B., M.B., F.R.C.P., F.R.S., Medical Officer Local Government Board, (Fellow), on Diphtheria; its Causes and Prevention.

LARYNGOLOGICAL SOCIETY OF LONDON.—At 5 p.m., Annual General Meeting. Dr. Bronner: (1) Osseous Nasal Obstructions removed by Cutting Trephine; (2) Aseptic Laryngeal Syringes.—Dr. Percy Kidd: (1) Recurrent Papillomata of Larynx twice operated on by Thyrotomy; (2) Angioma of Larynx.—Mr. L. A. Lawrence: (1) Hypertrophy of Posterior Faucial Pillars; (2) An Intra-Laryngeal Mirror.—Dr. Scanes Spicer: (1) Multiple Laryngeal Papillomata removed from a Child of Eight Years; (2) Papilloma of Uvula.—Mr. W. R. H. Stewart: Carcinoma of the Œsophagus.—Mr. Charters J. Symonds: (1) A Doubtful Laryngeal Case; (2) Diffuse Syphilitic Laryngitis.—Dr. Watson Williams: Epithelioma of Soft Palate. Annual Dinner (Café Royal, at 7.15 p.m.

HUNTERIAN SOCIETY.—At 8.30 p.m., Dr. Fletcher Beach: Sporadic Cretinism (illustrated by specimens).—Mr. Openshaw: Twenty-two Consecutive Cases of Amputation of the Breast.

THURSDAY, JANUARY 11TH.

BRITISH GYNÆCOLOGICAL SOCIETY.—At 8.30 p.m , Annual General Meeting; Election of Officers.—Dr. Benington: Notes of a Case of Ruptured Tubal Gestation; Operation eighteen months previously for a similar condition.—President's Valedictory Address.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—At 8.30 p.m. Dr. Remfry: On the Use of Ergot.—Dr. Beevor: A case of Cerebral Tumour.

FRIDAY, JANUARY 12TH.

CLINICAL SOCIETY.—Dr. Soltau Fenwick: Acute Phthisis following Destruction of Mucous Membrane of the Stomach by Corrosive Fluids. —Dr. W. J. Tyson: A case of Suppurating Hydatid of the Liver opened through the Chest.—Dr. J. W. Washbourn and Dr. E. W. Goodall: Cases of Membranous Inflammation of the Throat during Scarlet Fever.—Dr. Hale White: Diphtheritic Peripheral Neuritis causing Sudden Death.

Vacancies.

Armagh Union—Kendy Dispensary.—Medical Officer. Salary £120 per annum, with fees, and £20 per annum as Medical Officer of Health. Election—Jan. 17th. (See advt.)

Central London Ophthalmic Hospital, Gray's Inn Road, W.C.—House Surgeon. Rooms, coals, and lights. Applications and testimonials to the Secretary on or before Jan. 10th.

Cheshire County Asylum, Upton, near Chester.—Junior Assistant Medical Officer (unmarried). Salary £120 per annum, with board, lodging, and washing. Applications and testimonials to the Medical Superintendent on or before Jan. 15th.

City of Manchester.—Medical Officer of Health. Salary £850 per annum. Applications and testimonials to the Lord Mayor on or before Jan. 18th.

Hospital for Consumption and Diseases of the Chest, Brompton.—House Phyiscian. Applications and testimonials on or before Jan. 18th.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance. Applications and testimonials to the Chairman on or before Jan. 16th.

Salford Royal Hospital.—House Surgeon. Salary £80 per annum, with board and apartments. Applications and testimonials to the Secretary on or before Jan. 15th.

University College of South Wales and Monmouthshire.—Lecturer on Materia Medica and Pharmacy. Stipend £50 per annum. Applications and testimonials to the Registrar on or before Jan. 27th.

Appointments

ASHBY, A., M.B.Lond., F.R.C.S., Medical Officer of Health to the Reading Town Council.

BARTON, S., M.D.Dub., M.Ch., L.M., Medical Officer of Health for St. Faith District of the Norfolk Union.

BAINTON, R. D., B.A., M.D.Cantab., M.R.C.P.Lond., Assistant Physician to the Grosvenor Hospital for Women and Children, Vincent Square, Westminster.

CAMERON, W. S., M.B., Ch.B.Edin., a Medical Officer for the Mildura Shire, Victoria, Australia.

HOLMDEN, F. A. A., M.A., M.B., M.C., Surgeon-Captain to the Bechuanaland Border Police.

HOOPER, F. L., M.R.C.S.Eng., a Health Officer for the New Mornington Shire, Victoria, Australia.

JONES, F. F., M.R.C.S., D.P.H. Lond., Medical Officer of Health for the Combined Sanitary Districts of the Llanfyllin Union.

MCILRAITH, C. H., M.A., M.B., C.M. Glas., Resident Medical Officer to the Hospital for Diseases of the Throat, Golden Square, W.

REID, R. S., L.R.C.P., L.R.C.S.Edin., Surgeon-Major to the New Zealand Artillery Volunteers, New Zealand.

SINCLAIR, W. W., M.B.Aber., Senior House Surgeon to the Birmingham and Midland Eye Hospital, Birmingham.

STANFORD, W. B., M.R.C.S., L.R.C.P., Assistant Medical Officer to the Islington Infirmary, Upper Holloway.

TEMPLE, L. D., M.B., C.M. Glas., Medical Officer of Health for Saddell.

WATTERSON, J. W., M.B., C.M.Edin., Medical Officer of Health to the Morecambe Local Board.

WOOD, W. R., L.D.S.R.C.S., Dental House Surgeon to Guy's Hospital.

Births.

DODSON.—Jan. 3rd, at Hughenden, Earlsfield, S.W., the wife of Arthur E. Dodson, M.R.C.S., of a daughter.

POWELL.—Dec. 27th, at Round Hill Villa, Brighton, the wife of Walter A. Powell, M.R.C.S., L.R.C.P.Lond , of a son.

STROVER.—Jan. 4th, the wife of Herbert C. Strover, L.S.A., L.A.H., of Ivel Lodge, Sandy, Bedfordshire, of a daughter.

WELLS.—On Dec. 28th, at 8 Belsize Park, London, N.W., the wife of Poulett Wells, M.B., of a son.

Marriages.

BINDLOSS—BRUCE.—Jan. 2nd, at Christchurch, Lancaster Gate, Arthur Henry Bindloss, B.A., B.C., M.B.Cantab., M.R.C.S., L.R.C.P.Lond., of Harrow-on-the-Hill, to Lucy Veronica, daughter of the late Colonel Edward Bruce, Royal Artillery.

EMMET-CHASEMORE.—Jan. 1st, at St. Peter's Church, Croydon, John William Emmet, M.R.C.S., L.R.C.P.Lond., to Amy, third daughter of the late Henry Chasemore, J.P., of Croydon.

LANGRAN-POWNE.—Jan. 4th, at St. Mary's Church, Chard, Somerset, Bartholomew Langran, L.R.C.P.Ed., of Liverpool, to Agnes, third daughter of William Powne, L.R.C.P.Lond., and niece of Dr. R. L. Powne, Chard.

PALK-BARRON.—Dec. 18th, at the Cathedral, Bombay, Surgeon-Captain Charles H. Leet Palk, Indian Medical Service, 2nd Infantry, Hyderabad Contingent, to Eliza E. Gordon Barron, widow of the late John Barron, D.P.W., and only daughter of Colonel E. Gordon Lillingston, Indian Staff Corps.

Deaths.

BROWN.—Dec. 30th, at Gloucester Place, Edinburgh, James Kemp Brown, M.B., C.M., B.Sc., aged 28.

FORBES.—Aug. 14th, at sea, Charles Frederick Forbes, M.B., C.M., second son of the late Charles Forbes, M.D., Fleet Surgeon, R.N., aged 36.

GOOD.—Jan. 5th, at St. Neot's, Huntingdonshire, Frederick Thomas Good, M.R.C.S., aged 83.

GORE-GRAHAM.—New Year's Eve, at Assouan, Egypt, Isabel, wife of Surgeon-Captain Gore-Graham, Egyptian Medical Service, and eldest daughter of Sir T. Longmore, M.D., C.B., of Woolstone, Hants, aged 31.

MARSHALL.—Dec. 31st, suddenly, from an accident, near Wastwater, Arthur Milnes, aged 41, Professor Owens College, Manchester, and second son of W. P. Marshall, Birmingham.

GULL.—Jan. 2nd, at 2 Gloucester Street, London, W., Susan Anne, Dowager Lady Gull, widow of the late Sir William Gull, M.D. aged 74, after two days' illness.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

THE ETIOLOGY, SPREAD, AND PREVENTION OF DIPHTHERIA. (a)

By THORNE THORNE, C.B., F.R.S., M.B.,

Medical Officer of the Local Government Board, Lecturer on Public Health, St. Bartholomew's Hospital, &c.

BEFORE discussing the etiology of diphtheria we shall find it very useful to study its incidence, and this I propose to enable you to do by the aid of a map on which the shading indicates roughly the extent to which it has prevailed in the various parts of the kingdom. The depth of the shading indicates the incidence of the disease, and where this has been greatest it has been calculated at from 150 to 190 per 100,000 of the population, for England being taken at 100. In other parts less deeply shaded it falls as low as 50 to 80 per 100,000. The dark portion of the map lies in the main down the Eastern coast of England, and the next large patch of black covers the principality of Wales. You will see that the great midland centres have been to a great extent free from the disease, a fact which is of considerable importance, as you will see when we come to consider the distribution of the disease in rural and urban districts respectively. This distribution favours the view that the occurrence of diphtheria is favoured by cold and wet. You all know what the climate of the Eastern coast is like. This part of England is exposed in the first instance to wet and cold from the North Sea, and the East coast is certainly the most wet and the coldest part of the country. Wales, on the other hand, comprises both high lands and low lying valleys. The higher parts are cold, but in Wales it is probably more damp than cold that encourages diphtheria. The absence of diphtheria down the centre of England is the more remarkable seeing that the area comprises the valleys of several of our largest rivers where there is necessarily much moisture. There is the Thames, the Severn, &c., yet in spite of this these regions, as you see, rejoice in a certain degree of immunity from the ravages of diphtheria. What the reason of this may be I do not know, but my conviction is that running water is a very different thing so far as disease production is concerned, to permanent and stagnant wetness of the soil. We have several allusions in the Bible to the advantages of "living waters," as they are called, meaning of course running waters. These have health-giving properties which the other does not possess.

The first fact that must strike one's attention is that diphtheria has considerably increased among us since it was first recognised in this kingdom. That was in the 'forties when it was imported from France under the name of "Boulogne sore throat." It was at first an essentially rural disease. It spread mostly in the hamlets and the sparsely populated districts. By and bye there came a change in the incidence of the disease. At the present moment we find that diphtheria is raging in our large urban communities, in our great centres of population which were originally almost free from the disease. There is still an excess in the rural districts, taking the population as a whole, but a change has come to pass in virtue of which cities which were formerly almost exempt from the disease now suffer in a steadily increasing degree, and diphtheria bids fair to become one of the diseases of urban centres. This, I need hardly point out, is a very serious state of affairs. Recently we have had a very exceptional amount of diphtheria in London. The Registrar-General's returns for a series of weeks show that the deaths from diphtheria have ranged from 80 to 90 per 100,000, amounting during one week to 103. Such a thing has never happened before in the history of London since the disease made its appearance in the metropolis. The disease has now abated to some extent, and this fact enables me to point out that diphtheria has its seasons. The diphtheria season commences about the middle of September and goes on to the end of November. It decreases during December and continues to do so until March or April when there is another elevation, though much less in amount, the so-called spring incidence, finally there is less diphtheria during the summer than at any other time of the year.

Age affects the death rates from diphtheria in a very remarkable manner, as is shown by the Registrar-General's reports. Taking the proportion of deaths per 100,000, the deaths under 10 years of age vary from 15 to 70. The moment you pass 15 years of age, up to 20 or 25, instead of 43, 70, 64, 71, the deaths drop suddenly to 1, 2, 2, 2, 1, and so on, and after 25 years of age diphtheria ceases to be very fatal in this country. Moreover, the deaths from diphtheria over that age occur principally among those who are brought into close contact with those suffering from the disease, such as nurses and medical men. The greatest age incidence then is between 3 and 10 years of age.

Sex appears to have some slight influence in determining a liability to the disease, though this influence is not well marked. More females die from the disease than males, but this may arise from the fact that females are more exposed to infection than males. Little girls when they are sick are not nursed by boys, but little boys who are ill are often nursed by girls, and the same holds good later on in adult life. Men do not usually nurse women suffering from diphtheria, whereas men are necessarily nursed by women. A fallacy therefore underlies the figures bearing on the incidence of the disease as it affects the sexes.

Another very important point is the effect of unfavourable sanitary surroundings in favouring outbreaks of the disease. I have expressed an opinion on this point which is by no means universally received, though the matter has been discussed at great length in the columns of the medical press by various well-known authorities. Some observers think with me that the influence of insanitary surroundings has been greatly exaggerated; others hold that too much importance cannot be attached to insanitary conditions in its causation. One eminent medical man was heard to remark that he had never gone over a house in which a case of diphtheria had occurred without finding some defect in the drains or sanitary arrangements, but I doubt if I could visit any house except my own that did not present defects of some sort. I wish it to be clearly understood, however, that I have not taken up a position antagonistic to the view that the sanitary condition of a dwelling may influence the disease, but I do maintain that this influence is overwhelmed by other and more important conditions.

(a) Delivered at the Sanitary Institute on January 10th, 1894.

To make this clearer, let us consider some facts in relation to the mortality from typhoid fever in the country, in London, and, for a shorter period, in some of our large towns. Typhoid fever is essentially a disease associated with bad sanitary circumstances, and it responds more than any other disease to improvements in sanitary arrangements. The saving of life in this country, owing to this diminution in the enteric fever death rate, has gone hand in hand with the improvements in sanitary legislation. England is the admiration of the world as the country in which comparative immunity from typhoid fever has been purchased by extensive sanitary improvements, and I hope we may continue to merit the palm in this respect. Early in the seventies the death rate from enteric fever was practically 40 per 100,000. It has since gradually fallen to 20, 26, 23, then still further to 17 or 18, where it now is. This means an annual saving of many thousands of lives, and the general mortality has followed the same lines. The same decline has taken place in London, where the death rate now varies between 12 and 15 per 100,000 per annum. We have therefore a great drop from 37 per 100,000 in the seventies to 19 in 1893. This period of twenty years, I need hardly remind you, has been characterised by enormous progress in sanitary administration. If, therefore, diphtheria be due to faulty sanitary conditions, we ought to be wiping it out, a little at any rate, whereas we find that it has, on the contrary, gone up by leaps and bounds. In 1872 the mortality was 9 per 100,000, while in 1890 it was 18, that is to say, just double. In London it began by killing 9 in 100,000, then 12, 14, 17, then 22, 23, and finally 39 and 33, and it has been even higher than this during the last two years, in fact, it has nearly trebled, and this, if you please, during the very period that sanitary circumstances have been undergoing every kind of improvement. I will not go so far as to say that sanitary conditions have nothing to do with the production and spread of the disease, but it is certainly curious, to say the least of it, that coincidently with our boasted improvements, the mortality from this cause should have doubled and even trebled. I was asked before a Royal Commission not long since what I thought as to the influence of water in spreading the disease. I was told that a certain eminent physician had been to a house where diphtheria had broken out; he had found something wrong in the well, and he had pointed to the defect in the well and the disease as cause and effect. Now we have been working at the Local Government Board for twenty years on the subject of diphtheria, and in no single instance has it occurred to any one inspector to identify water as the probable cause of diphtheria. Bad water may of course prove harmful to individuals, and by lowering their standard of health, predispose them to any infection to which they may be exposed, but I am confident that there is no direct relationship between polluted water and diphtheria. As a matter of fact the diphtheritic organism finds it very difficult to live in water. It can indeed only live in very polluted water, and average water is to a large extent destructive of vitality.

Putting water infection on one side much more interest attaches to the possible influence of imperfect drains and sewers. The period over which our statistics extend is the period during which our sewerage system has been mended and amended and improved to an extraordinary extent. Millions have been spent in bringing them up to date, yet diphtheria has not diminished; on the contrary, it has gone on increasing. Again, it has been especially in our large towns that these improvements in sewerage have taken place. Early in the seventies, however, before they were commenced, there was not much diphtheria in our towns. It is since these improvements have taken place that diphtheria has made its appearance in our cities on a large scale and has carried everything before it. It is evident, therefore, that there can be no direct connection between bad sewerage and diphtheria.

Now, diphtheria is essentially an infectious disease. The emanations from the throat and mouth are intensely infectious. By expectoration and otherwise the poison gets into the sewers and cesspools, and in that way I do dare say they may become contaminated by diphtheria, and so the disease may be caused by emanations from a diphtheria-infected drain. Just in the same way as the sewers, the soil itself may become contaminated. I am convinced that there is some relationship between the influence of soil and diphtheria, and this influence appears to vary with movements in the level of the sub-soil water. In river valleys especially there are constant oscillations of the sub-soil water. When the water level rises the diphtheritic and other organisms in contaminated soil are washed up and their emanations are expelled, and so diphtheria may possibly be caused. The possibility of such a sequence of events may therefore be conceded. We hear sometimes of what is called "drain-throat." I do not know exactly what this may be, but it seems certain that people who inhale effluvia from drains (and the better the house the more pipes are there to convey the noxious vapours into the interior) do get a form of sore throat, just as medical students and nurses in hospitals get what is called "hospital sore throat." There are thus two ways in which the sore throat caused by sewer emanations may lead to diphtheria. I have a strong impression, though I might not be able to prove my contention, that diphtheria never attacks a healthy throat. I will not undertake to say what constitutes a healthy throat, it may be merely some change in the alkalinity of the secretions,

However this may be, from the moment you get an inflamed and denuded sore throat there is nothing the diphtheritic organism likes so much as to fasten upon it. Drain emanations, therefore, do not, strictly speaking, cause diphtheria, but they prepare the soil for the development of the specific organism of the disease.

I am credited with having started a diphtheria theory of my own. One can never be sure of the amount of originality that can fairly be claimed in such a matter, but it so happens that in making some investigations on outbreaks of diphtheria in certain parts of the country I have had my attention called to circumstances the like of which have been observed by others. Take, for example, the Welsh valleys. There we find houses built upon the slope of a hill, built right into the hill, so that the walls are always wet and the floor is always mud. During the cold weather the people all get sore throats, and if you look into their throats you will almost always find traces of ulceration due to past attacks of inflammation of the tonsils. The sore throat—an ordinary sore throat, so far—is passed from one to the other (for all forms of sore throat are apparently infectious), and by-and-bye—as I myself have observed over and over again—it gets worse and worse until it culminates in an outbreak of diphtheria. The explanation that occurred to me in respect of these circumstances is a progressive increase in the infectiousness of the organism which produces diphtheria. There is nothing irrational in such a view, although certain distinguished bacteriologists did not take kindly to the idea. They hold that just as cats, cows, and dogs always produce cats, cows, and dogs, so the various micro-organisms must also breed true. To some extent, and in respect of certain organisms, this may be so. If you go to a house where there is measles you do not expect to catch whooping-cough nor scarlet fever where a patient is suffering from typhoid, but it seems to me that some diseases are probably more stable than others, and I think diphtheria is among the unstable, and that it is capable of acquiring disease-producing properties which it did not previously possess. This is the property of progressive infectiousness to which I have alluded. We know that if you take a wild plant from the heath where it has great difficulty in keeping alive at all, and place it in a hothouse under specially favourable circumstances of temperature, soil, &c., it will in a few generations develop properties vastly different from those it originally possessed while growing on the heath, and if relegated to the heath once more after a time it gradually loses these properties and returns to its original condition. If we apply this train of reasoning to the organism of diphtheria it will be seen how, under favourable conditions of environment and soil, it may develop properties which it did not possess in the first instance. Dr. Adams, of Maidstone, who has given special attention to the subject, remarks that "again and again epidemics of diphtheria arise from a number of ordinary and apparently non-specific sore throats."

There is another form of sanitary circumstances which is more difficult to deal with, viz., manure nuisances, but there does seem to be some relationship between these and the production of diphtheria. Certain it is, by coincidence or otherwise, that outbreaks of diphtheria have occurred at places along the Thames where London manure is deposited, and it is quite possible that the manure may have been the vehicle of transmission of the poison, especially since it has become so general in our midst.

Before dismissing the assumed tendency of the diphtheria organism to settle down upon any sore throat, there to determine its own disease, I may mention that a definite relationship has been alleged to exist between scarlet fever and diphtheria. Now, I have never seen or heard of a case in which scarlet fever followed diphtheria, while there are hundreds of instances in which the patient convalescing from scarlet fever has contracted diphtheria. This, I maintain, is only another example of the tendency of the diphtheria organism to attack sore throats generally. The scarlatinal sore throat affords the organism the gate of entry where it can fix itself and develop under favourable circumstances.

Diphtheria, as I have already pointed out, is a disease specially prone to attack children between the ages of 3 and 10, or 5 and 12, but it is very difficult to determine for certain how far it is simply a question of age. We must remember that it is at the age of 5 or 6 that children begin to go to school, and 5 to 15 may be regarded as the "school incidence," though plenty of children go to infant schools even before that age. I remember my attention being called to this circumstance when inquiring into an outbreak in a village in Essex in which upwards of 1,400 persons were attacked, though it was spread out over a long period of time. There were 272 cases under 3 years of age, but between 3 and 12, the special age incidence, the number was 928, and between 12 and 15, covering the remainder of the period, the number was 210. This clearly shows the special incidence affecting children between the age of 3 and 12. But, of course, the majority went to school at that age, so I had to separate those who went to school from those who did not. I found that while among those who were known to go to school, the proportion was 59 per cent., the proportion between 0 and 3 (before the school age) was only 1 per cent, and only 5 per cent. among those, aged between 3 and 12, who for any reason did not go to school. That has been worked out in detail by my friend, Mr. Power, whom I consider to be the greatest etiologist of the day. He has succeeded in showing that not only is the incidence greater among those who go to school, but that by the mere aggregation of children in school it is easy to manufacture a marked degree of malignancy.

He went down to investigate the outbreak in a district in which it was possible to know every child and to follow their movements. The schools were in working order, and, taking the age incidence between 3 and 12, he found that 16·6 per cent. of those attending school had contracted diphtheria as compared with 3·8 per cent. among those who did not go to school. While dealing with this point, I must remind you that children who contract diphtheria at school may easily carry the infection to others who remain at home, so that this proportion of 3·8 per cent. is possibly susceptible of a reduction. The schools were closed for many weeks in order to try to get rid of the disease by eliminating all children with sore throats. Then came the second period. The schools were reopened and 4·8 per cent. of the scholars contracted diphtheria, whereas none of those who stayed at home caught the disease. Again, the schools were closed and greater precautions were ordered, no child being allowed to return to school whose throat on examination was not perfectly sound. Again the schools were reopened, and this time the proportion attained 7·1 per cent. among those who went to school, while only 2·5 per cent. of those who did not go were attacked. The schools were closed afresh, and this time the medical officer of health himself undertook to examime the children as to the condition of the throat, and the teachers were instructed to refuse every child who was unwell in the slightest degree. Nevertheless, on the fourth reopening, 4·1 per cent. of the children contracted the disease. Between these periods there was not a single case of sore throat known to exist anywhere. Now this seems very remarkable and the events show very clearly the influence which school life exercises on the spread of diphtheria.

The next step is to consider how and why schools should thus favour the spread of the disease? The first thing to notice is that it brings together the most susceptible members of the community under circumstances which are peculiarly favourable to this kind of infection. The children are close to each other, and in saying or singing their lessons they have every facility for breathing into the faces and mouths of their near neighbours. Consequently a child with a trace of diphtheria can easily infect the others. The Education Department requires so much wall space and floor space, but if you have ever been into one of these schools you will have observed that of the available floor space fully two-thirds are monopolised by the teacher while the children are piled up at one end, so that the object of giving so much floor space is frustrated. The greater the want of ventilation the greater the risk. Then too, children of young age are very fond of passing on sweets from mouth to mouth, and of drinking out of the same unwashed cup, thereby offering greater opportunity for serial infection.

It is the aggregation under these circumstances that recalls to my mind the experiment with plants removed to the hothouse. The children are brought together, they are aggregated in a sort of hothouse, there is a want of ventilation, there is overcrowding, in fact, special facilities are afforded for infection from one to the other—every circumstance that theoretically would tend to aggravate the virulence of the diphtheritic poison.

It may be advisable to say something as to the means of prevention. I am afraid the school attendance officers are largely responsible for spreading the disease. They stimulate attendance without inquiring whether or not the child had been kept at home on account of sore throat. This leads me to direct your attention to what has been going on in England during the last 20 years or so. During this period the organisation of elementary education has made vast strides. It began, of course, in the rural districts where the parson worried every child into attending school. Indeed, I am afraid the parsons have largely contributed to the spread of the disease in this way, though I willingly recognise the purity of their motives. It was years before the increase was seen in London, but some change has evidently come to pass in London and other great cities, whereby diphtheria has been enabled to take a hold among our urban populations, and this change, in my opinion, is compulsory education, acting, as I have said, by causing the aggregation of the most susceptible members of the community under conditions favourable to the spread of diphtheria. Of course we cannot stop elementary education, but it may be possible to modify the circumstances which I have shown to be potent factors in spreading the disease.

The next question is the possibility of infection by milk. A large number of outbreaks of diphtheria have been distinctly traced to milk, and many of the most obscure outbreaks in former years would have been easily explained had this method of infection then been recognised. The milk may be infected by reason of the presence in the dairy of a person suffering from the disease, for if the germ falls upon the milk this affords it an excellent medium for growth and development. I do not, however, think that this is often the case. A far more frequent cause in my opinion is the existence of a disease in the cow itself. In inquiries into certain outbreaks it has been shown inclusively that the disease followed particular "milk walks," that is to say, the *clientèle* of particular dairymen. It has even been traced to particular sheds and finally to particular cows. Of course you must allow for secondary infections, so your inquiries must bear on the first cases only. Of course, a considerable number of the persons who drink the milk escape, but this cannot excite any surprise. It is a common experience. It was, however, noticed that children who were habitual milk consumers suffered the most, whereas those who took little milk and that little either boiled or only in tea, &c., escaped. Again, those who took cream suffered more than those who did not, an observation I had already made in respect of typhoid infection. I took this to be merely the mechanical effect of the oil globules in rising, taking with them the germs to the surface. With regard to diphtheria however, Mr. Power has shown that this is not the case. He finds that those who take fresh milk suffer less than those who take skimmed milk or cream, and the point with him is the keeping the milk too long. If you partake of an infected milk while it is yet fresh you only take a certain, probably a small, dose of the poison, because the germs have not had time to multiply to any great extent. If, on the other hand, you take milk that has been standing 24 hours, the germs have had plenty of time to develop and multiply and the dose of poison is proportionally greater. The lesson to be learned is to leave off drinking raw milk altogether, and you will escape many diseases, diphtheria among the number. I believe we are almost the only nation addicted to drinking raw milk. Some tribes in India would no more think of drinking raw milk than of eating raw flesh, but whether they rejoice in any immunity from diphtheria from this cause I cannot say.

The relationship of the lower animals to man in respect of infection is interesting from every point of view. Many of the lower animals have been suspected of constituting a danger in regard to diphtheria—cats for example. The question may, of course, be asked whether it is the cat that gives the diphtheria to the child or the child to the cat. One thing is certain, viz., that the cat can be inoculated with human diphtheria and suffers from definite well-marked and specific symptoms typical of this particular disease, and that the diphtheria organism can be found in its dejections. Although I have little doubt as to the possibility of a diphtheritic cat passing on the malady to the child, I do not think much diphtheria is contracted in this way. But there is the cow! When these outbreaks were traced back to particular sheds there was always the possibility of finding cows suffering from some disease. Now, our knowledge of the diseases of cows is very vague. There is so much that is unknown with regard to diseases associated with vesicles and pustules of the udder that one is touching upon difficult ground. The fact remains that one frequently finds that the cows have been suffering from a disease associated with a rise of temperature and the formation of vesicles and pustules upon the udder, the animal being evidently out of health. You can often trace the disease actually to the particular cow, and the cow was always affected in this way. An objection that is frequently urged in such cases is that there was someone on the farm who was suffering from diphtheria and who might have contaminated the milk. But there is nothing extraordinary in some of the persons on the farm being affected. It would indeed be extraordinary were it otherwise, for they are naturally the first to be exposed to the infection. If you take diphtheritic matter from a sick child and inoculate a milch cow—it is essential that it should be a milch cow—Dr. Klein has found that the animal developes a disease which, he says, he is absolutely unable to distinguish from that found in the cow living in the sheds to which the milk has been traced. On the fifth day vesicles, pustules, and ulcerations make their appearance, and material from the vesicles contains the typical organism as found in the human subject. He inoculated a cat with it, and the cat developed diphtheria. Still further, some of the milk from this diseased cow was accidentally given to a cat, and the cat developed typical diphtheria. That alone I think is quite sufficient to show that there is a field calling for further investigation.

I have a firm impression that a large number—if not, indeed, the great majority—of our specific diseases come to us through the lower animals, or have come from them in the past. I have just said that diphtheria is not a stable disease like certain others, but for this very reason I think we ought to lose no time in taking the necessary measures to diminish its incidence before it has had time to become stable, and we must not allow ourselves to be deterred from taking these measures in a matter of such importance by the plea that they will interfere with somebody's trade.

Now as to prevention. We must bear in mind that diphtheria is essentially an infectious disease, and the most frequent source of infection in this country is certainly infection from one person to another. It is, therefore, necessary to isolate patients, and in most cases this can only be done by isolation in hospital. Those who have visited isolation hospitals on a large scale will admit that the system is not altogether satisfactory. The mortality, moreover, is terrible, without one being able to say why. This may be due in part to the fact that probably only the severer cases reach the hospital, but I am convinced that the principle of aggregating patients suffering from infectious diseases in hospitals is altogether wrong. On the other hand, the advantages to such infectious patients of special care, nursing, feeding, and medical attendance may more than compensate for the enhanced risk. Nevertheless, we must never lose sight of the fact that hospital construction entails one great evil—the aggregation of the infectious sick.

What we require is a large amount of air space, but that means money, in construction, land, management, &c. What we really want is linear space, and I care nothing for mere cubical measurement. A hospital may be as lofty as you please, but if the patients are packed closely together on the floor the ventilation will be deficient, and the place will be unhealthy. Efficient ventilation, which means a large amount of wall space, is the only way to avoid the evils of aggregation.

Where sore throat ends and diphtheria begins I cannot say, but no child who is suffering from any form of sore throat should be allowed at school, nor even anyone from the house in which that child resides. In regard to the closing of schools, the Education Department makes some allowance when the school is closed by order of the medical officer of health, so that the grant may not be lost on the ground of diminished attendance. It may not, however, be always desirable or necessary to close the schools altogether. Let us take the example of a particular district. There is a central village in which the church and school are situated together, with several outlying hamlets, A, B, C, and D. An outbreak of diphtheria may occur at C. Of course, no children from that hamlet ought to be allowed to attend school, but it would be a mistake to close the school altogether, because then the other children would have time and opportunity to frequent C and to catch the disease. While they are at school, at any rate, they are protected against this particular source of infection. Unfortunately, the Education Department makes no provision for this contingency, and the school suffers in grant by reason of the non-attendance of the scholars from C. This is a discrepancy which ought to, and probably will, receive immediate attention at the hands of the Department.

There are many other points which I should have liked to discuss, but the subject is as wide as it is interesting, and I have been obliged to restrict myself to a somewhat desultory sketch, necessarily brief, of some of the principal points concerning the incidence and spread of this terrible malady.

◆

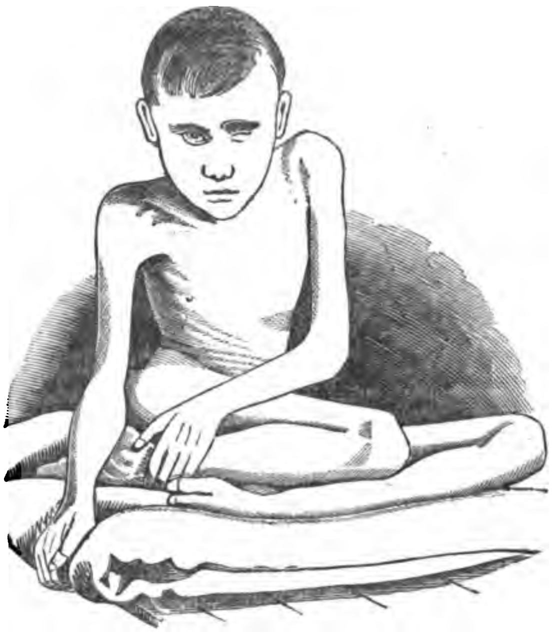
REPORT OF FIVE CASES
OF
PSEUDO-HYPERTROPHIC PARALYSIS OCCURRING IN ONE FAMILY.

By J. CHRISTIAN SIMPSON, M.B.

Pseudo-hypertrophic paralysis was first noticed by Sir Charles Bell in 1830, though it was somewhat confused with progressive muscular atrophy, which was presumed to be a later stage of the pseudo-hypertrophic condition. In 1847 Partridge recorded some cases, but it is to Meryon in 1852, and to Duchenne in 1861, especially the latter, that our present classical description is due. Since Duchenne's latter contributions, and Griesinger's description of the living pathology in 1865 and 1868, the knowledge of the disease, as regards its etiology and treatment, has not materially advanced, though the clinical features are well brought out in Dr. Gowers' collection of 220 cases recorded up to 1879, and during the next ten years the number came up to 280.

Samuel B., æt. 7, born at Wishaw, complained of weakness and enlargement of the calves of the legs, difficulty in rising off a seat or the ground. Duration about 21 months.

History.—Patient's relations are all healthy so far as known; no consanguinity in the parents, nor evidence of any neurosis. He is the sixth in a family of ten, there being two years interval between each member. The eldest is a boy, æt. 15, who was apparently well till he was ten years old, when he began to show some stiffness and awkwardness in rising off a seat, shortly after a severe attack of measles. Then waddling walking developed, the calves were seen to be enlarged, and spine curved and the shoulders prominent. He has gradually become weaker and has now been bedridden for two years. He is much emaciated, and only slight movement of the arms remains; legs very contracted, and atrophied; spine greatly curved antero-posteriorly and laterally when he is raised in bed, though not so marked when recumbent. The facial and lingual muscles appear still hypertrophied; organic reflexes are normal, and no sensory or trophic lesions of the skin are present; fair mentally. The second in the family is a girl, æt. 13, healthy; the third, boy, æt. 11, affected; the fourth, boy, died young of bronchitis; the fifth, boy, died young of bronchitis ; the sixth, boy, æt. 7, affected, the seventh, boy, æt. 5, affected; the eighth, boy, æt. 3, affected; the ninth, girl, 17 months, apparently well, and the tenth, boy, 6 months old in January, 1890, well.



State on Examination of Samuel, Oct. 17th, 1887.—Well-nourished as regards body generally, erect attitude is peculiar, the legs being wider apart than normal and one planted forward. There is lordosis and compensatory curves in the dorsal and cervical regions. He waddles much, and is awkward and inaccurate in most movements. The movements performed to attain the erect attitude are characteristic, as is also his method of rising off a seat and ascending stairs. Was at school when 4 years old but left 15 months later, when the waddling and enlargement of the calves began. The tongue is large, causes some thickness of speech, and is protruded between the teeth during sleep, he snores much. Other system normal. In examining the muscles, the order in which they are most often affected will be followed, and given in tabular form.

Region.	Muscles.	Condition.
Legs	gastrocnemius	hypertrophied
	vastus externus	,,
	hamstrings	,,
	gluteus maximus	,,
	adductors	normal (?) atrophied
	quadriceps extensor (rest of)	,,
	anterior tibials	,,
Arms	rhomboids	hypertrophied
	supra, and infra-spinatus	,,
	triceps	,,
	supinator longus	,,
	flexor sublimis	,,
	deltoid	atrophied
	pectoralis major	,,

Arms	latissimus doris	atrophied
	biceps	normal
	trapezius	"
	sterno-mostoid	"
Trunk	erector spinæ	hypertrophied
	rectus abdominis	"
Head & neck	sterno-mastoid, trapezius	normal
	masseter	hypertrophied
	facials	"
	linguals	"
	temporals	normal
Involuntary muscles		"

Muscles not mentioned are either normal or could not be definitely said to be atrophied, on account of their position. All found hypertrophied are noted.

The circumference of the right calf was 12 inches, and of the left, 11½. The circumference of the right gluteal fold was 12½ inches, and of the left 13 inches. Slight talipes equinus, more on the right side. The circumference of the right upper arm was 6 inches, as were also the measurements of the left upper arm, and right and left arms just below the elbow. Shoulder girth was 23½ inches. The atrophy of the latissimus dorsi allowed of alar scapulæ. A plumb line from the most prominent point of the back falls just behind the heels, and 3½ inches behind the extreme concavity of the lordosis. A plumb line from the most prominent point of the abdomen falls 7½ inches in front of the heels, when the patient stands easy—toes 12 inches apart and heels 7½ inches apart. Abdominal girth was 22 inches. Thus there is a simultaneous and symmetrical hypertrophy of some, and atrophy or normal condition of certain other muscles of the body, and those hypertrophied, though in different degrees, have all the same palpable characteristics. No gross or fibrillary twitching was seen in any muscle. Bones and joints normal except those involved in the talipes and spinal curvature.

Nervous System.—Common and special senses normal, though muscular sense doubtful. Pupils and their reactions normal. Organic reflexes normal. Superficial reflexes: plantar, cremasteric, abdominal and scapular normal, Central deep reflexes: no ankle clonus, front tap nor tendo-achilles reflex. Patella tendon reflex on both sides but no clonus. Brachial reflexes: no supinator, biceps nor triceps tendon reflex. Co-ordination normal, except where marked paresis. Electrical reactions mostly normal to both currents. Vaso-motor and trophic functions normal except in the muscles. Mental state fair.

Samuel's elder brother, æt. 11, the third in the family, is in a more advanced stage. Face broad and stolid looking, tongue more troublesome, lordosis and alar scapulæ more marked. Walking very waddling and unsteady, organic reflexes normal, sensory functions normal, superficial reflexes present, but deep reflexes absent. Muscles more hypertrophied or atrophied than in Samuel.

James, æt. 5, is less affected than Samuel, and a boy, æt. 3, has some of the primary symptoms, though no marked muscular change is evident. This completes the account of the five members affected. In 1890 I ascertained that the eldest boy died of bronchitis shortly after I saw him in December, 1887; John was bedridden, and the others all advancing.

Remarks.—There is no hereditary nervous or muscular complaint, no consanguinity, and the girls are so far healthy. Measles appears to have been the exciting cause in the case of the eldest boy, but there is no history of any exanthem preceding the appearance of symptoms in the other cases. Though the eldest boy was ten years old when attacked, the seventh and eighth in the family were æt. 5 and 3 respectively, and the symptoms seemed to develop more rapidly. The majority of recorded cases are said to be congenital or to appear before the age of six years.

The three stages are well shown. The first stage, altered function, a paresis before any gross muscular change is evident, is present in the younger two boys, who are awkward and have difficulty in some movements. The second stage, that of hypertrophy and atrophy of certain muscles with commencing compensatory deformity, such as lordosis, is shown in the next two boys, æt. 7 and 11. The third stage, that of secondary atrophy, progressive deformity and paralysis, is marked in the eldest boy, who was bedridden for nearly three years before his death, and whose sole voluntary movement of limbs or trunk, consisted in slight motion of the arms.

The muscles affected and not affected, though to some extent, erratic, are largely members of a group which has a definite action, and this distribution is to some degree independent of the apparent nerve supply. The antagonistic muscles are often in the opposite condition or appear normal. Thus, taking the muscles around the shoulder-joint and arm, we find that the deltoid, pectoralis major, and latissimus dorsi, which are atrophied, are supplied by nerves passing through the three cords of the brachial plexus, but through other branches of the same plexus and cords, muscles either normal or hypertrophied are also supplied, such as the biceps, brachialis anticus which are normal, and the triceps, supinator longus, and flexors which are hypertrophied. This is shown in the annexed table:—

Nerve.	Muscle.	Condition.
2nd sp. n. and sp. acces.	sterno-mastoid	normal
3rd and 4th and "	trapezius	normal
5th sp. n.	rhomboids	hypertrophied
Suprascapular and 5th and 6th	supra and infra-spinatus	hypertrophied
Brachial Plexus—		
Outer cord.		
Ant. thor., ext. div., 5, 6, 7	pectoralis major	atrophied
Musculo-cutan., 5, 6, 7	biceps	normal
Median ext., div., 5, 6 7	flexor sublimis	hypertrophied
Inner cord.		
Ant. thor., int., div., 8, *id.*	pectoralis major	atrophied
Median int., div., 8, *id.*	flexor sublimis	hypertrophied
Ulnar, 7, 8, *id.*	flexor ulnaris	hypertrophied(?)
Posterior cord.		
Subscapular, 5, 6, 7, 8	latissimus dorsi	atrophied
Circumflex, 5, 6, 7, 8	deltoid	atrophied
Musculo-spiral, 5, 6, 7, 8	triceps	hypertrophied
Musculo-spiral ext. div.	supinator longus	hypertrophied

If the cords are still more analysed, muscles innervated from the same spinal root are found to be in different conditions, and these states seem to correspond rather to the physiological action and co-operation in performing certain movements, than to the anatomical nerve supply, as is shown in the preceding table.

Facts such as these, especially when combined with absence of sensory, trophic or electrical changes, in the first and second stages at any rate, incline one to discard a purely nervous etiology. In many cases the spinal cord is normal, in some there have been observed collections of leucocytes and patches of inflammatory softening around the blood vessels, while in others there is some congenital malformation or deficiency. The patches of softening are most probably secondary, or occur in very advanced cases, and the congenital malformations are, may be, only an accidental extension of a more widespread embryological defect in the mesoblast, which accounts for the primary muscular changes. This is the more probable as the majority of cases are congenital or appear in the early years of life.

I have to thank Dr. Affleck, in whose wards in the Edinburgh Royal Infirmary some of these cases were, while I was his Resident Physician, for kind permission to use the notes on them.

Tunbridge Wells.

Vienna Clinical Lectures.

LEPROSY.

By PROFESSOR KAPOSI, M.D.,
Vienna University.

[SPECIALLY REPORTED BY OUR AUSTRIAN CORRESPONDENT.]

UNDER this term a disease has been isolated which appears from history to be of ancient origin, dating from the time of Moses. Though common, and probably often epidemic through centuries, no clear definition or description appears to have been on record until about the fortieth year of the present century. Its European history would seem to have commenced about the beginning of the Christian era, after which we hear of it becoming pandemic and isolating hospitals erected for the separation of the lepers.

It appears to have been viewed with considerable alarm, as very many stringent laws have been enacted in different States to protect the healthy; we read of the lepers being prohibited from marriage, that they shall not be allowed to speak to the healthy, when on the street or public road they must announce their presence by the ringing of bells, &c., &c.

From ancient history we must infer that its presence was widely diffused among the different nations and described in the Bible under the designation of "Zarad," a term which has undergone transformation by the Greek translation, but handed down to us now as leprosy. The Greeks translated the disease as Elephantiasis, but included under this term a number of diseases which are now known not to be leprosy at all. "Zarad" cannot be accepted as clearly describing all the cases of leprosy mentioned in the Bible. If a person got scalded or burnt the natural result would be a large cicatrix which under the Levitical diagnosis would receive the name of "Zarad" and be treated as such. The Greeks included under Elephantiasis, Psoriasis and other affections of that character allied to leprosy. In Arabia, on the other hand, the term was widely used and the disease often confounded as Elephantiasis Arabum. In Germany, the disease is known as "Aussatz," from the patient being exposed, which seems to agree with the Lepra Arabum, and Elephantiasis Græcorum. The Lypra Græcorum seems to be more closely in accord with Psoriasis, while the Elephantiasis Arabum corresponds with our Pachydermia. In the general public "Aussatz" includes itch owing to its transmission, while Lepra is reserved for the more severe forms of the disease.

Leprosy began to fade in Europe about the fifteenth century or shortly after the discovery of America, at which time another complication in the nosology of the disease arose in the form of syphilis, which was held to be a modified form of leprosy at that time, and the infected were similarly treated and confined in leprosy hospitals. The syphilitic attacks at this time seem to have been very numerous, and naturally excited terror in the whole districts where these so-called lepers were to be found. The healthy or unaffected fled in fear with the object of escaping from the infected inhabitants. These examples I merely relate to state the inherent feeling at that remote date of infection which is even now a burning question. About 1848 two men, Boeck and Danielssen, of Christiana and Bergen, published an extensive description of the disease, which led Boeck subsequently to visit the Mediterranean Coast, where a malady under the name of hospital disease was very common on the sea board districts. Since that time our scientific classification of leprosy has been arranged under the name Elephantiasis Græcorum. At the present time, however, leprosy is accepted as a more correct term of that specific disease which will be noticed later.

It has been recently observed that the disease is peculiar to many of the Eastern districts, South Sea, the Riviera, Marseilles, &c. Closer investigation with more correct diagnosis has confirmed its presence over a wide area, and in Europe the larger numbers are to be found in Greece, Norway, the Crimea, and Constantinople. A peculiar feature in the disease is its rapid development in a district where a few years before a single case may not have been known, of which North America is a good example. It is presumed that a few cases were imported to the Sandwich Islands where in a short time 4,000 were found congregated, which has now rapidly increased to 20,000. These facts tend to point to convection of a specific poison, although definite proof is not yet forthcoming. A few recorded districts in the neighbourhood of Riga and St. Petersburg have a similar history.

When we examine the symptoms of leprosy and endeavour to arrange them in types, I find that three groups can be clearly classified, although Danielssen and Boeck have only described two of these. First, *lepra tuberosa* is that form of tubercle which arranges itself under the skin in small particles ranging from the size of a pea or lentil to that of fine shot. The appearance of the skin at this stage may be unchanged, or it may have already taken on a brownish red or glazed colour, giving the patient the appearance of a gypsum statue painted brown. The skin is somewhat thickened and raised in the course of the disease, giving a false idea to the observer that the nodules are diminishing. The latter are usually between the size of the syphilitic and lupus nodules, selecting the eyebrows and forehead as their favourite site, where they are usually found closely set together, although other parts of the body are not unknown to their first appearance. After a case has developed itself for a year or so it is easy to make a diagnosis forty yards off from the striking appearance of these nodules and the colour of the skin. Two or three months may pass away without any apparent change in the nodule; after two days' fever the nodules may begin to diminish; on the other hand, after many years stationary, may again begin to increase. In the region of attack, which we have stated to be the eyebrows, the hair begins to fall off, exhibiting deep furrows between the incipient nodules, giving a morose appearance to the sufferer; next the genitals and hands are attacked, and finally the whole body. Apparent gumma begin to form in the throat, impeding the vocal cords, and produce aphonia. When the larynx is examined these nodules may be observed under the mucous membrane, having a greyish covering over the surface. All these forms of superficial infiltration are usually classed under the probably correct term of lepra tuberosa.

We may here note another variety, *lepra mutilans*, where it happens to appear over joints or succeeding other inflammations, with large gangrenous patches, which is also easy of diagnosis. There are some varieties of this class, however, that may lead to considerable doubt on the first examination, for instance, when a patient comes to you for the first time with a large nodule over the præputium; such a case I usually mark with caution, and note if it be diffused, or having the glazed infiltrated nature absent, which leads me to conclude that syphilis is not the cause.

After a few years' duration the phenomenon may assume an anæsthetic appearance sometimes in the region of the nodule, at others only in the region of the infiltration. In the course of the tenth or fifteenth year, complications usually arise of a fatal nature, as tuberculosis, &c., and death speedily ensues. The second form of the disease is *lepra maculosa.* It sometimes appears simple and undisguised, while on other occasions it is mixed up with lepra tuberosa. This is generally classed as a type of third form, the *lepra anæsthetica* which might as correctly be termed a type of lepra tuberosa which has the anæsthetica phenomena also.

Amongst the fixed forms between the tuberosa and anæsthetica the peculiar nature of lepra maculosa can be distinguished on the skin as white and brown patches with anæsthetic points, while the tactile sensibility in all the patients is normal. Next comes the true *lepra anæsthetica* without any patches or nodules from the beginning of the disease to the end of it. There are varieties of this form in which the patches originated with a vesicle and desquamation, leaving the site as an anæsthetic patch. There are other cases where the skin is perfectly normal with the exception of these anæsthetic areas. The anæsthesia appears to commence centrally and to extend by its circumference coinciding in this respect to the supposition that the bacilli form a central inflammatory point and extend peripherally by infiltration. All these forms may undergo change and assume different conditions according to the diminution of the infiltration. Besides these, are other cases where high fever is present, which, however, are far more frequent in the tubercular form, being distinguished by atrophy of the musculi interossei, &c., probably due to metastasis. In a close examination of the question of infection there is great diversity of opinion. The most recent hypothesis is founded on the lepra bacillus which must first gain admission to the person affected. Direct transmission by experiments have been made in both man and animals but as yet no positive proof can be placed before us; still less proof offers help in our general experience. In my daily visits I am constantly meeting with leprous patients who come from districts where no leprosy can or has existed, again, there are people who leave a region perfectly free from leprosy, go to South America and there reside two, three, or four years, returning home quite free of leprosy; on the other hand, people similarly free, go to reside in places where the disease is present and return in the course of a year affected with leprosy. It is evident from these facts that infection cannot be excluded, neither can we with confidence assert that it is included. We have other people living under the same conditions, and in so close communion with them, that the bacilli may be easily transmitted as in the case of food or clothing. We have other records from medical men practising in leprous regions who tell us that two married people having lived 20 years together, one of them contracts leprosy, the other is free and never takes it who is probably descended from a leprous free family. This hypothesis throws in our calculations the theory of heredity to some extent, but how far it can be depended upon is yet problematic. We may, therefore, conclude that infection is not clearly established and that the victims to this disease should be treated as humanely as circumstances will permit, and not as outcasts or loathesome exiles, as the past history of the disease can testify. On the other hand, it must not be forgotten that our fellow creature requires equal protection, and that authorities should be advised to be careful in the formulating of laws with respect to this disease. Whether it can be directly inoculated from a leprous nodule I am unwilling to deny, but must admit there are many exceptional cases. In regard to the treatment of this terrible disease, whether it be infectious or not, we have no known potent remedy against its progress. I think every possible drug has been tried, from creosote injections to the most innocent inunction to prolong life, but of all the efforts removal of the patient to a leprous free district seems to be the most reasonable and efficacious; but healing or recovery can scarcely be hoped for. Doubtless, there are many publications propounding different treatments that have met with perfect success and total recovery, but their confirmation can only be found in the printer's ink. In some cases temporary improvement may be observed by increasing the general nutrition, stimulating the appetite, open air exercise, general hygiene, and medicated baths.

◆

A NOTE ON

YAWS (FRAMBŒSIA):

ESSENTIALLY A DISEASE AFFECTING THE NEGRO RACE—ITS HISTORY—ETIOLOGY—PATHOLOGY—COURSE—SYMPTOMS AND TREATMENT.

By CHARLES FORBES, M.D., C.M., D.P.H.Cantab.,

Nazirah, Assam, late Surgeon Wassa Gold Mines.

This short note, for which I must apologise in the matter of its brevity, is an attempt to place a modern face on a complaint which was known to both English and foreign surgeons in the last century as being imported from the Guinea Coast of Africa to the West Indian Islands. It is a constitutional disorder attended often with fever and always by a peculiar papular eruption; sometimes, however, the button-like marks are elevated, and have an almost crimson appearance like that of a wild raspberry, hence its name. At this time the papules are very vascular and readily bleed, like condylomata. It is limited to West African negroes or those of negro descent, very rare among whites. These men taken as slaves to the West Indian Islands and Spanish Main.

John Hunter describes a case of yaws; this is proved to be of syphilitic origin by the very pains he takes to prove it is not. Then follow essays by James Thomson, Paulet, Rollet. Lancereaux, "Sur la Syphilis," has made a careful *précis* of the literature relating to this subject. J. W. Hulke, F.R.S., and Dr. Hebb have also discussed publicly some points of its resemblance to syphilis.

Etiology.—Its probable cause was syphilis being spread among the negroes of West Africa by European traders.

Proofs of its venereal origin are as follows, viz.:—

(1) That it is contagious and can be inoculated in the same manner as matter taken from an indurated chancre. Paulet inoculated a child with virus taken from a papule for two or three weeks; the marks persisted as red scratches; at the end of three weeks they became ulcers with an indurated base; at the end of seven weeks an eruption broke out all over the body, which persisted for nine months.

(2) That it is accompanied by ulcerated throat and pains in the bones.

(3) That the eruption is of a secondary specific type, though not of the usual lean ham colour but yellowish white, having, however, an ulcerative tendency.

(4) That it is transmitted by parents to their offspring.

(5) That such children infect those who suckle them.

(6) That the disease is much improved by mercurial treatment.

(7) The pathological histology of the papules resembles the tissues found in syphilitic gummata was stated by Dr. Hebb, and this I can fully confirm.

The above seems to me almost overwhelming evidence in favour of the theory that yaws is a disease of syphilitic origin.

Diagnosis.—Easy, once seen it is never forgotten. My first case was a Fantee; expression anxious, his body and limbs wasted, his voice metallic, and his whole body covered with yellowish white patches varying in size from a shilling to a florin ; these stood out in bold relief against his dark skin.

Symptoms and Course.—Negro complains of general malaise, fever, and pains in head and bones, which are worse at night, and ulcerated throat. The typical rash appears with the formation of papules which break down and ulcerate under a scab often with great loss of tissue. If patient is secluded carefully the disease may run its course in seven months. Some cases appear, however, even after treatment to redevelop symptoms markedly syphilitic ; occasionally intercurrent phthisis ends the scene.

Pathology is that of secondary syphilitic lesions well known to all.

Treatment, which I found most effective among natives of West Africa, being one tabloid of calomel, gr. j, three times a day, also with pulv. opii, gr. ⅛ for each dose, to be persisted in until patient's gums were affected. At this point the treatment should be changed. One tabloid of potassium iodide, gr. v., and two of soda mint being administered three times a day. For the cutaneous eruption an ointment:

℞ Ungt. hyd. ammon. dil., ʒij ;
Ungt. zinci oxidi, ʒij ;
Lanolin, ʒiv.
Ft. ungt. bis die utend.

is very efficient. For ulcerated throat, spray of corrosive sublimate lotion 1 in 1,000 by means of an atomiser. Should cutaneous ulceration prove extensive and phagedænic, dusting with dermatol powder greatly assists granulation and epithelial formation ; the diet should be nourishing and non-stimulating, the results being, under these conditions, most excellent in my tropical practice.

◆

Selected Prescriptions and Therapeutic Notes.

18. **Pruritus Vulvæ.**—The following are in use at the principal Paris hospitals :—

℞ Phenic acid, ʒj ;
Sulph. of morphia, gr. x ;
Boric acid, ʒij ;
Vaseline, ℥iiss.
or
℞ Cod-liver oil,
Oil of tar, } ʒiiss ;
Lanoline,
Nitrate of silver, gr. vj.
or
℞ Phenic acid cryst., grs. xx ;
Distilled water, gr. 100.

Inject every two days one drachm of this solution in the region of the trochanter. Very successful.

From our French Correspondent.

19.—**Sir Andrew Clark's Treatment of the Cough at Puberty** :—

R Glycerini boracis, ℥j ;
Bismuthi oxichlor., ʒij ;
Morphiæ hydrochlor., gr. 2½.
M. Fiat applic.

This application should be brushed over the whole interior of the throat after each meal, and also at bedtime. For internal administration the following are of use : A syrup of the bromide of quinine and iron, with small doses of arsenic ; also a pill of reduced iron, valerianate of zinc, belladonna and nux vomica. This latter, often successful in controlling the cough, must be given in doses slowly increased until the physiological effects of the belladonna become apparent, and then slightly diminished.

20.—**Local Application for Diphtheria** :—

℞ Camphor, ʒv ;
Castor oil, ʒiv ;
Alcohol, ʒijss ;
Carbolic acid (crystals), ℈iv ;
Tartaric acid, gr. xvij.
M. Sig. For local application.

La Tribune Médicale.

21.—**The following is a Good Ointment for Hæmorrhoids** :—

℞ Cocaine hydrochlor., gr. xx ;
Morph. hydrochlor., gr. v ;
Atropiæ. sulph., gr. iv ;
Pulv. acid. tannici, gr. xx ;
Vaseline, ℥j ;
Ol. rosæ, q.s.
M. Sig. Apply after each evacuation of the bowels.

22.—**Menthol in Pruritus** :—

℞ Menthol, gr. xxv ;
Lanoline, ℥j.
M. F. ung.

23.—**Tincture of Iodine as a Counter-irritant** :—

Hammond recommends a mixture of glycerine and tincture of iodine when the latter is required to be applied to the skin for the purposes of counter-irritation. The iodine acts more powerfully under these circumstances, owing to the fact that the glycerine prevents the drug from volatilising.

24. **Aconite in Cancer.**—Mr. Jonathan Hutchinson asserts that tincture of aconite is decidedly useful in the treatment of painful cancers. In one case, a lady took ten minims of the drug three times a day for a whole year. The drug never disagreed with her, and she thought the pain had to some extent been controlled in consequence.

25. **Local Application for Gout.**—The following will be found useful :—

℞ Flexible collodion, 5 parts ;
Ether, 5 parts ;
Salicylic acid, 4 parts ;
Hydrochlorate of morphia, 1 part.
M. This should be painted over the affected toe.

26. **Constipation in Infants** :—

℞ Manna, ʒxij ;
Calcined magnesia,
Sublimed sulphur, } āā ʒiiss ;
White honey, ʒviiss.
M. Sig. One or two tablespoonfuls in a cup of hot water.—DR. FERRAND.

27.—**For Whooping-Cough** :—

℞ Bromoform, gr. x.
Alcohol, ʒj.
Distilled water, ℥iij.
Simple syrup, ʒiij.
M. Sig. One or two teaspoonfuls daily.—*Revue de Therap.*

28.—**Pills for Hæmoptysis** :—

℞ Powdered ergot,
Powdered extract of rhatany, āā ʒj.
Extract of belladonna, gr. v.
Powdered digitalis, gr. x.

Make into forty pills. From four to six to be taken for a dose.—DR. DE MOUSEY.

◆

IN reply to a deputation which attended at the Treasury on the 12th inst., Sir William Harcourt promised to subsidise the Welsh University College with £3,000 for the present year, but would make no promise as to the future.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, Jan. 12th, 1894.

The President, Mr. J. W. Hulke, F.R.C.S., in the Chair.

Dr. Soltau Fenwick on a case of

ACUTE PHTHISIS FOLLOWING DESTRUCTION OF THE MUCOUS MEMBRANE OF THE STOMACH BY CORROSIVE FLUIDS.

A potman, æt. 34, was attacked with the symptoms of severe gastritis after swallowing some oxalic acid with intent to destroy himself. For six weeks pain in the epigastrium was a constant symptom, and vomiting ensued on every attempt to swallow nourishment. The patient's strength was fairly maintained by means of nutrient enemata, but he lost several stone in weight. After two months the stomach was found to be considerably dilated, the lower margin extending below the navel. Tenderness on pressure existed over the pyloric region, and vomiting occurred at intervals and resulted in the rejection of large quantities of a sour, fermenting fluid which was devoid of any trace of free hydrochloric acid. With the systematic employment of lavage considerable improvement manifested itself in the general condition of the case. The patient steadily gained flesh, and in the course of the next two months increased his weight by nearly 18 pounds. The vomiting was also relieved, and the gastric pain lessened in severity. Four months after the onset of the disease the patient caught cold, he shivered, and the temperature, which had previously remained at a subnormal point, rose to 102 deg. Cough, sweating, rapid emaciation, with recrudescence of the gastric symptoms, developed themselves, and death ensued within six weeks from acute phthisis. The autopsy revealed a condition of caseous tuberculosis invading both lungs from apex to base, with a small vomica in the right upper lobe. The stomach was greatly dilated, and its lining membrane converted into a shining layer of fibrous tissue with numerous radiating bands. No trace of glandular structure could be detected by the microscope. *Case* 2. A gentleman, æt. 32, accidentally swallowed some nitric acid in the spring of 1888. When he came under observation three months later he was found to be suffering from some degree of dysphagia, with pain in the epigastrium and occasional vomiting. The stomach extended about one inch below the umbilicus, and a distinct splash was audible on palpation, with marked tenderness on pressure over the pyloric region of the stomach. When a tube was passed a slight constriction was encountered at the lower end of the œsophagus. The contents of the stomach consisted of a brownish-coloured, sour smelling fluid, in which no trace of free hydrochloric acid could be detected. The stomach was subsequently washed out every day and food administered regularly by means of the tube. Under this treatment the patient rapidly improved, the vomiting and epigastric pain became less severe, and the body weight steadily increased. About seven months after the accident the patient began to suffer from cough, night sweats, and the temperature, which previously had remained below the normal point, now rose to over 102 deg. F. These symptoms rapidly increased in severity, the gastric phenomena reasserted themselves, and the physical signs of progressive consolidation of the lungs became manifest. Death ensued from exhaustion at the end of seven weeks. At the autopsy the lungs were found to be the seat of acute tubercular affection from lung to base. The mucous membrane of the stomach was completely destroyed, and was represented merely by a thin layer of fibrous tissue. The lower few inches of the œsophagus showed evidence of superficial cicatrisation of its mucous membrane, and at the pyloric end of the stomach a chronic ulcer was discovered, the contraction of which had caused stenosis of the pyloric orifice. In the "Bulletins de la Société Anatomique, of Paris," M. Robert gives the details of an almost precisely similar case, in which destruction of the secreting surface of the stomach by nitric acid, was followed by an acute tubercular affection of the lungs which proved fatal from pneumothorax in five weeks. These cases are of interest from the fact that in each a corrosive fluid had completely destroyed the digestive activity of the stomach with a fatal issue after an interval of a few months from acute pulmonary phthisis, in spite of the fact that there existed no family tendency to this disease. It would, therefore, seem that the sudden impairment of nutrition in these cases so diminished the resistance of the tissues as to render them peculiarly vulnerable to tubercular invasion.

Mr. Barker asked what means were adopted for the purpose of ascertaining the presence of free hydrochloric acid in the stomach contents?

Dr. Glover, in reference to the first case, asked whether there was any tubercular history either in the family or in the patient?

Dr. W. J. Tyson said the question was whether the phthisis was *post hoc* or *propter hoc*. He asked whether phthisis frequently followed gastric ulcer or abrasion of the gastric mucous membrane?

Dr. Longmore observed that in the absence of any history of tubercular disease it was interesting to endeavour to ascertain how the infection could have been conveyed. He doubted the existence of any direct connection between ulcer of the stomach and tubercular disease of the lung.

Dr. Chapman inquired if any raw meat juice had been given?

Mr. Hulke remarked that there were physiologists of the present day who taught that in some animals the stomach was an organ that could be dispensed with, *e.g.*, in dogs the stomach had been excised and the duodenum united to the œsophagus with no obviously harmful effects.

Dr. Fenwick, in reply, said that he had used Gunzburg's test to ascertain the presence of free hydrochloric acid. It was claimed for this test that a ten-thousandth part of the free acid could be detected. In the first case there was no phthisical history, and the patient had previously exhibited none of the physical signs or symptoms of tuberculosis, nor was there any phthisical history in the second case. No raw meat juice had been given. Dittrich had stated that 20 per cent. of the cases of gastric ulcer died of phthisis. His own view was that if a man in previously good health has had gastric mucous membrane destroyed with resulting emaciation he rendered himself much more vulnerable to tubercular infection.

Dr. E. W. Goodall and Dr. J. W. Washbourn on

CASES OF MEMBRANOUS INFLAMMATION OF THE THROAT DURING SCARLET FEVER.

The authors described a fatal case of a membranous inflammation of the throat accompanied by a rash. The diagnosis rested between—(1) Severe scarlatina anginosa with membrane ; (2) Diphtheria with rash ; (3) Co-existing scarlet fever and diphtheria. Subsequent desquamation and an absence of diphtheria bacilli on a careful bacteriological examination proved that the case was one of scarlet fever with membrane. The difficulty of diagnosis was due to the remarkable toughness and thickness of the membrane. Such a condition is uncommon, although it is well known that a membranous inflammation of the throat indistinguishable from diphtheria is quite common during the acute stage of scarlet fever. This condition has been found not to be true diphtheria by various bacteriological investigators. The authors examined four cases of this nature, and failed to find diphtheria bacilli. Clinically, too, it is not diphtheria, for out of 123 cases seen by the authors only 2 developed croup and 2 subsequent paralysis. On the other hand a membranous inflammation of the throat occurring during convalescence from scarlet fever is generally true diphtheria. In 4 cases examined by the authors they readily found diphtheria bacilli by cultivations, and they have notes of 11 cases in which the membrane spread to the larynx, of 3 cases which were followed by paralysis, and of one case in which the vulva became affected with diphtheritic inflammation. In 8 consecutive uncomplicated cases of diphtheria the bacilli were readily demonstrated. The conclusions drawn were that a membranous inflammation of the throat occurring during the acute stage of scarlet fever is generally not true diphtheria, but a similar condition occurring during convalescence is true diphtheria. These conclusions are in accord with the bacteriological examinations made by several investigators abroad and by Klein in this country.

Dr. Sidney Martin said that the nature of the non-diphtheritic membranous sore throat was an interesting question. Trousseau had recognised and described it, but it now appeared to be the habit to regard all membranous sore throats as necessarily diphtheritic. Diphtheria, he remarked, might be defined as an acute infective disease, the membrane from which on cultivation yielded a specific bacillus producing a poison which, on inoculation to animals, caused paralysis. He referred to a case in which there were patches of membrane on the fauces, tonsils, and pharynx. Cultivations from this membrane gave only a large diplococcus. Such cases yielded to local treatment with nitrate of silver. In another and severer case, in a young girl of 15, who was an out-patient at the Brompton Hospital, the symptoms were those of scarlet fever, with enlargement of the spleen and asthenia associated with some redness of the throat. She died, and post-mortem two patches of membrane were found, one on the rim of the epiglottis and the other on one of the tonsils. Microscopically there was found an abundance of micrococci, which had invaded the tissues of the tonsil and epiglottis. It differed in this respect from the diphtheria bacillus, which never penetrated below the surface. He believed that the membranous sore throats of scarlet fever were produced by micrococci and various other organisms not diphtheritic. The throat already attacked by scarlet fever was rendered less capable of resisting the invasion of other organisms.

Dr. Hale White asked when the membrane developed? He referred to the case of a medical student who was seized with a rigor at 4 a.m. He had been exposed to both scarlatinal and diphtheritic poison. By the afternoon his temperature was 103° F., the throat was red, and there were small patches of membrane on the uvula, pharynx, and posterior pillar of the fauces.

Dr. Glover asked whether the patient had been exposed to scarlatinal poison, and as to the proportion of diphtheria cases that presented a scarlet rash?

Dr. Benham admitted a doubt whether scarlet fever and diphtheria were really distinct diseases. He referred to an instance in which, in a house with three children suffering from scarlet fever, a man developed diphtheria, and he referred to the observations of Dr. Parsons, who, in a report of the Local Government Board on a certain epidemic, remarked that the two diseases seemed to be intercommunicable. He had recently seen a membranous sore throat develop in the course of a case of acute pneumonia.

Dr. Turney said that when the membranes were limited to the fauces it might possibly only be an exaggeration of the condition of ulceration which was often seen in scarlet fever, and which might even extend to the trachea. He had seen such ulceration recur two or three months after the scarlatinal attack.

Dr. Goodall said that it was important to determine the etiology of these cases, for if they were really a mixture of scarlatina and true diphtheria they might give diphtheria to the scarlatinal convalescents in a ward. He himself was strongly of opinion that the great majority of such cases were simple scarlatina. When there was membranous sore throat in scarlatina it did not spread to the larynx, and did not recur locally as was the case in diphtheria. The membrane usually developed exceedingly early. No history of exposure to scarlet fever could be obtained in the case. Rashes were uncommon in diphtheria, but they did occur sometimes, and were then limited to the trunk, and were darker than the scarlatinal rash.

Dr. Washbourn, in reply, said that true diphtheria and scarlet fever might sometimes occur concomitantly. The only way to differentiate between them was by bacteriological examination. He had seen cases of ulceration of the larynx in scarlet fever, but it was never accompanied by membranous exudation.

Dr. W. J. Tyson read a paper on

A CASE OF SUPPURATING HYDATID CYST OF THE LIVER OPENED THROUGH THE CHEST WALL.

F. G., æt. 31, a laundress. In 1888 she suffered from a slight attack of jaundice, and again in January, 1892, on the 8th of February following was admitted into the Victoria Hospital, Folkestone. On admission the liver was found to be enlarged, extending below the ribs for four inches; all other organs healthy; the evening temperature was 101° F. A week after admission signs of pleuritic effusion into right chest developed, and the liver had now reached as far as the pubes; the evening temperature remained high. On February 27th, 23 ozs. of serous fluid was drawn off from the right side; on March 3rd, the posterior part of the chest was again aspirated, and an ounce of puriform hydatid fluid escaped. March 5th.—An incision was made into the 8th intercostal space posteriorly, 3 inches in length, as soon as the pleural cavity was opened about an ounce of fluid flowed out, immediately an elastic swelling presented itself, the cyst wall of which was stitched to the external wound, the cyst was then laid open and 30 ozs. of thick pus full of skins of all sizes escaped; the cavity was not washed out; a large india-rubber tube, 6 inches in length, was put in. External dressings of gauze and wool were then applied. There was experienced no difficulty in putting in the uniting stitches between the wall of the cyst and the skin wound on account of the wide separation of the adjoining ribs. For the first three days after the operation about half a pint of pus and "skins" passed and the cavity was washed out with boracic acid solution through the tube. On March 13th, the breathing became audible over the base of the right lung, and the liver dulness had disappeared. The discharge gradually became less, but the tube, although shortened from time to time, was not finally removed until February, 1893. *Remarks:* The case when first seen was thought to be one of simple enlargement of the liver, but the rapid increase in its size with the high evening temperature pointed to a suppurative condition of the organ. The presence of the pleuritic effusion is worth noticing. There was never any sign of the liver contents entering the thoracic cavity after the operation. In such liver abscesses as the one described the opening through the chest wall posteriorly seems to be the proper route to take, as being more direct and better adapted for drainage.

Mr. Wallis remarked on the position of the hydatid in the convex or posterior wall of the liver. He observed that the position by which the hydatid had made its way through the diaphragm into the pleural cavity had not been clearly explained. He did not altogether agree with the method of operation that had been adopted and he suggested that it would have been better at first to have made merely an exploratory puncture with a hypodermic needle, and then later on to have excised a rib or two when they would have dealt radically with the hydatid. If the hydatids were still living the cyst wall could have been pulled out, or if suppurating, it could have been treated as an ordinary abscess.

Dr. Hale White referred to an almost exactly similar case under his own care. The chest had been tapped in August for what had been regarded as a simple pleurisy with effusion, but the patient presented herself at the hospital recently with indications of a thickened pleura. At a depth of three inches from the surface purulent fluid was drawn off by the aspirator. The liver extended well below the ribs. A portion of the eighth rib was removed and the whole pleura found full of dead hydatids. The liver bulged up into the wound and a needle inserted into it evacuated some thin pus. A knife was passed along the needle track and the incision enlarged, when an immense number of living hyatid cysts were turned out of the right hepatic lobe. Soon after the patient was seized with dyspnœa and died, and at the autopsy the right lung was found to be the size of a man's fist, lying against the upper part of the spine. The left lung was healthy. The diaphragm on the right side had become exceedingly thin and atrophied, and in its centre it merged into the top of the liver. The left hepatic lobe had become hypertrophied so as to be almost as large as the right, the latter being occupied by an enormous hydatid cavity.

Sir Dyce Duckworth objected to the practice of washing out these cysts, and preferred the policy of non-interference provided a sufficient exit were made, a large drainage tube put in and the patient kept in a proper position and surgical cleanliness adhered to. He thought that the majority of hydatid cysts and empyemata did better under this plan than when they were washed out.

Mr. Hulke pointed out that the great tendency in these cases was for the abscess to burst upwards. The cases which ruptured upwards could be divided into two classes, viz., those in which the hyatid burst into the lung first and caused a secondary empyema, and those in which the rupture took place primarily into the pleura. In the first class there was decided risk in washing out, for these cases resembled an empyema communicating with a bronchus. In one case which had been irrigated with iodine, traces of that substance were detected in the expectoration. He believed that the introduction of a small quantity of iodoform emulsion would naturally assist in keeping the cavity sweet.

Dr. Tyson, in reply, observed that the case was one of suppurating hydatid from the beginning. The first tapping emptied the pleura only, but the second entered the liver and evacuated the pus. A case of suppurating hepatic hydatid with ascites had been reported from Australia, but he believed that his was the first case in which the condition was associated with pleuritic effusion. He only commenced the washing out after a week when the pleural cavity had become shut off by adhesions.

◆

THE HUNTERIAN SOCIETY.

Meeting held Wednesday, Dec. 13th.

The President, Mr. F. Gordon Brown, in the Chair.

SPECIMENS.

Dr. **Charlewood Turner** exhibited two specimens of ileo-colic intussusception, obtained from patients both admitted on the third day, and both in collapse. In one case there was a tumour felt in the right hypochondriac and umbilical region.

Dr. F. J. **Smith** showed specimens of perihepatitis with abscess of the gall-bladder. The patient suffered from slight albuminuria and jaundice.

Dr. F. J. **Smith** also exhibited bacilli lepræ under the microscope; a specimen of enlarged gall-bladder due to impaction of a stone in the cystic duct; and a specimen of ruptured liver, kidneys, and fracture-dislocation of the lumbar column, due to being run over by a dray, where there had not been the least bruising of the skin.

Mr. A. H. **Tubby** showed the upper epiphysis of the humerus removed by operation from the shoulder-joint of a child suffering from abscess, rigor, and other signs of acute epiphysitis involving the joint. The head and bone lay loose in the abscess cavity. The child recovered.

Mr. **Charles Symonds** exhibited two appendices of young adults, one which measured 3 inches in length, was extruded from the aperture made for the relief of a perityphlitic abscess. The other was removed by operation in the interval between the attacks, from a young lady who had had three attacks of severe pain and threatening perforative peritonitis. The lady has since been free from any discomfort.

Dr. **Arnold Chaplin** exhibited a specimen of

AORTIC STENOSIS COMPLICATED WITH MALIGNANT DISEASE OF THE ŒSOPHAGUS.

The patient from whom the specimen was taken was a man, æt. 72, who was admitted into the Victoria Park Chest Hospital, complaining of pain over the cardiac region, palpitation, and dyspnœa. After being in the hospital some time, he improved somewhat, but complained of inability to swallow solid food. On making an examination the heart's apex beat was found to be displaced outwards and downwards, the cardiac dulness extended at the base of the heart across the sternum to the level of the second interspace. At the apex could be heard a short systolic murmur; at the base of the heart over the dulness there was a loud long rasping systolic murmur, conducted up towards the right clavicle. It was thought that slight pulsation could be detected to the right of the sternum. Behind, there was dulness to the left of the spine an inch or so above the level of the inferior angle of the scapula. The man subsequently died, after having suffered much from cardiac pain and increasing inability to swallow. Permission was obtained to examine the body, when it was found that the heart was enlarged and the left ventricle much hypertrophied. The aorta at its commencement was dilated, and the aortic valves were united together so as to form a slit-like aperture just large enough to admit the point of a knife; above this aperture and somewhat firmly adherent to the sides of the vessel a clot of fibrin was found about the size of a hazel nut, which still further closes the valvular opening. In the œsophagus opposite the commencement of the descending aorta there was a ragged ulcerated aperture, as large as a florin, and which was a mass of inflammatory tissue which has been removed. The bronchial glands were also infiltrated with this deposit which proved to be epitheliomatous. There was no deposit in other organs. The diagnosis in this case was the subject of much controversy, some maintaining it to be an aneurysm, others a new growth, while yet others believed it to be simply stenosis of the aorta. The symptoms were not indicative of one more than the other.

Dr. **Hingston Fox** showed the principal cerebral arteries, with numerous patches of atheroma upon them, taken from a man who died slowly of coma, with free hæmorrhage in the subdural space, and large clots pressing upon the convolutions of the middle third of the cerebrum. The pupil on the same side as the lesion was dilated, and there was rather less movement in the right arm and leg than in the left, though no actual paralysis existed.

◆

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Tuesday, January 9th.

The President, Mr. John Appleyard, M.B., F.R.C.S., in the Chair.

Hypertrophy of the Breast.—Mr. Horrocks read the notes of a case of mammary hypertrophy in a young unmarried girl. There was considerable œdema of the under surface of the breast, the whole organ was enlarged, and the nipple also enlarged; histologically there was a very great increase in the connective tissues and a relative decrease in the glandular structures of the organ.

Unusual case of Retardation of Labour.—Dr. H. Bronner narrated the case of a primipara in which the last stage of labour was extremely protracted and had to be terminated by instruments; the right arm was fixed behind occiput by two turns of the cord, and the left was bent across under the chin with the left elbow opposite the right ear, thus preventing flexion of the head.

Auricular Fistulæ.—Mr. Althorp read a paper on a case of auricular fistulæ, and dealt with the various structures occasionally persisting through life, which are examples of persistence of fœtal conditions. Messrs. Appleyard, Johnstone, and Horrocks, discussed the paper.

Meningitis in Rheumatic Fever?—Dr. Major read a note on grave cerebral symptoms arising in the course of rheumatic fever. No post-mortem evidence of cerebritis or meningitis is to be found in cases of acute rheumatism; the onset of cerebral symptoms practically means onset of hyperpyrexia, and that is what one ought to be suspicious of. Drs. Goyder, Kerr, Shiach, Arnold Evans, Johnston, and Wood joined in the discussion.

(From our own Correspondent.

Paris, Jan. 13th.

Acute Rheumatism in Children.

Having had a certain number of cases of rheumatism in children under treatment in his wards lately, Dr. Jules Simon, one of the best authorities on children, took occasion to give a lecture on the malady, of which the following is a brief analysis:—

Like adults, children can have rheumatism under its three forms, acute, subacute, and chronic, but the acute form is by far the most frequent.

However, the rheumatism is chiefly localised in children and often in the articulations of the vertebral column. The malady also affects simultaneously all the tissues of an articulation, and not only some of the elements as in the adult. Muscular rheumatism is also frequently seen in children, but cutaneous rheumatism is by far more frequent, constituting the origin of many eruptions. Acute articular rheumatism is rare over five years and under thirteen. When an articulation is affected the heat swelling and redness are not well-marked, although the pain may be very great, the inflammation is chiefly found in the synovial sheaths of the muscular tendons, over which pressure cannot be borne. Such a painful affection has been frequently confounded with "growing pains" to the prolonged suffering of the little patient. Some fever is present, but of an intermittent type, and frequently the heart is touched, but the endocarditis, unlike what is seen in the adult, tends frequently to terminate by resolution. Rheumatism of the cervical vertebræ and the muscles of the neck is very frequent in the age of childhood, and is not seldom confounded with incipient Pott's disease or wry-neck. Cutaneous rheumatism is frequently manifested by erythema localised or generalised, or by profuse perspiration occurring especially at night, and giving great uneasiness to the parents. These symptoms disappear, however, quickly under proper treatment. The nervous system is also frequently affected by rheumatism, of which chorea, meningitis, paraplegia, &c., are sometimes manifestations.

The treatment in general should consist in frictions with belladonna oil, wrapping the parts in wadding, and the internal administration of salicylate of soda.

Resection of the Inferior Maxillary Nerve.

At the Académie de Médecine, M. Quenu called the attention of his colleagues to a method of intracranial resection of the inferior maxillary nerve which he considered superior to those generally employed. In 1891 he had occasion to resect by Horsley's method (extra-cranial) the nerve in a man suffering from tic douloureux of the face. Ease was obtained immediately, but after some time the affection returned with its usual intensity. A second operation was made, and it was discovered that several small branches had escaped observation in the first operation, consequently the nerve had not been desected in its totality. This oversight suggested to him the replacing of the long, laborious, and uncertain method of Horsley, by an operation which would permit the section of the maxillary nerve before its entry through the foramen ovale.

To arrive at this result, several authors before him followed different methods. Thus, Horsley and Krause penetrated into the skull by trepanning the temporal region, while Salzer, Kronlein, and Rose sought the foramen ovale through the deep and narrow zygoma fossa. His (M. Quenu) manner of obtaining the same result differs a little from the above. Its execution is easy, as the nerve can be reached in five minutes. He makes a curved incision from the extreme apophysis of the orbital bone to the auditory canal. The apophysis is sawn at both extremities, and the flap which comprises the temporal is detached and thrown down. The trephining instrument is applied and the finger passed through the aperture thus made to detach the dura mater. The roof of the zygomatic fossa is then freed from its membranes with the rugine, and the finger again passed in until the foramen ovale is felt, its exact position being defined by the apophysis of the pterygoid bone in front and the spine of the sphenoid behind. A curved Cooper's needle is then introduced and the nerve hooked up, when it is easily resected.

Hysterectomy for Prolapsus.

M. Segond brought forward the question of treatment of prolapsus by surgical interference, and said that in vaginal hysterectomy the age of the patient should be taken into account. However, if there existed a neoplasm or some lesions of the appendages, the operation might be performed without any scruple before menstruation had entirely ceased, as the patient would be much better off without an organ which would be a continual source of danger to her. He had performed three hysterectomies last year which were justified by the fact that lesions of the appendages existed.

M. Richelot said that the first hysterectomy that he performed for prolapsus was on a woman, æt. 60, and the result proved to him the ease with which he could operate and the benignity of the operation, but also the possibility of a prolapsus of the vaginal walls, so that in some cases he had remedied by operation this infirmity. Consequently he thought that in many cases hysterectomy might be replaced by resection of the vaginal wall, and fixation of the uterus by narrowing the outlet.

M. Lucas thought that no matter what method was followed, a relapse could occur. Sims' operation was not bad, but Le Fort's was excellent. Fixing the uterus to the abdominal wall succeeds *au début*, but a relapse often takes place. Discouraged by all these methods, he invariably practised hysterectomy.

Iodoform Salol.

Salol has the property of combining with different bodies, camphor for instance, iodoform, aristol. To obtain this combination it is sufficient to heat the mixture of these agents to 104° F., when a liquid is obtained which solidifies at 77°. M. Regnie utilises the combination of salol with iodoform for the dressing of wounds when it is desired to obtain immediate reunion without suppuration. He paints over the sutures with the liquid, and in solidifying an antiseptic varnish is obtained protecting the wound and assuring rapid reunion.

Germany.

[From our own Correspondent.]

Berlin, Jan 12th.

The Influenza.

For the last two months the influenza has again been rife, and although its intensity has not been so great as in the winter of 1889-90, it has been greater than during the last outbreak. There is no doubt that a great amount of heavy work has been thrown on the doctors on account of it during the past few weeks. Between the dates Nov. 4th and Dec. 16th, 183 deaths from influenza have taken place in Berlin. An unfortunate victim to the epidemic has been Dr. S. Guttmann, as already announced, a Privy Sanitary Councillor and editor of the *Deutsch Med. Wochenschrift*. His illness was of a fortnight's duration, and he sank from cardiac paralysis following influenza. Like his cousin of the same name, Dr. P. Guttmann, Director of the Moabit Hospital, who fell a victim to the same disease in the early spring of last year, he was a man busily engaged both in practical work and in literature. Like many another well-known member of our profession, in early life he served in the army, and was engaged in the campaigns of 1866 and 1871, where he served with distinction. He received the Iron Cross of the 2nd Order, and was finally appointed Oberstabsarzt of the Landwehr. He came to Berlin soon after 1871 and commenced private practice. In 1874, however, he began writing for the *Deutsch Med. Wochenschrift*, which was founded in that year by Paul Börner. As collaborateur with this talented journalist he continued until the death of Hr. Börner in 1885, on which occurrence he undertook the sole management. Owing to his energy and talent this journal, which began with only a small list of subscribers, soon became a decided success, and one of the leading professional journals of Germany. It was a fortunate thing for it that it was the one selected by Koch for the publication of his discoveries with regard to tuberculine. In addition to this weekly Hr. Guttmann published the "Reichs Modizinal Kalender," the Year Book for Medical Practitioners, he also wrote largely on hygiene, professional questions, &c., and in 1889-90 brought out in connection with Prof. Leyden the large collective work on the influenza epidemic. He was also medical officer in chief to a life insurance society, and a busy practitioner among some of the leading families of the city. In the midst of this busy existence he unfortunately contracted the prevalent malady and cardiac failure, that typical scourge of the physician, put an end to his career. He was a comparatively young man, having been born in 1839. His successor as editor of the *Deutsch Med. Wochenschrift* is Prof. Guttstadt, Medical Statistician in the Royal Statistical Bureau.

NOTIFICATION OF PREMATURE AND STILL-BIRTHS.

A police notice has recently been issued to the effect—

1. That all births are to be notified by the midwife in attendance (*a*) of full time living children, (*b*) of all fœtuses that have lived, however short a time, even if only a few moments after separation from the mother, and irrespective of the stage of intra-uterine life and of viability.

2. That all still-births are to be officially notified (*a*) of full term children, (*b*) of all fœtuses of over the 6th month or 180th day of pregnancy, and of 32 or more centimetres in length, (*c*) of all fœtuses regarding which it is doubtful whether they have attained the age stated in (*b*) or not.

3. On the other hand the births of such fœtuses are not to be officially notified as are distinctly under the 6th calendar month or 180th day of intra-uterine life or as are of a less length than 32 ctm.

CAUTERISATION OF MUCOUS SURFACES AND MUCOUS SECRETIONS.

Prof. H. Köbner (*Berl. Klin. Wochensch.*) has a reference to this subject and points out that cauterisation of mucous surfaces of the buccal cavity, for instance, frequently fails of its effect from the eschar being wasted away too rapidly by the secretions. Making a note of this, he was next led to make the attempt to arrest the local secretion by the application of belladonna previous to the application of the escharotic. He succeeded in this by giving from twenty to forty minutes before applying the caustic, 20 minims of a 2 per cent. solution of belladonna, and repeated in from two to three hours, or at latest in the evening and the following morning. The procedure was found especially useful in ulcerations occurring in the course of treatment by mercury.

He was afterwards led to attempt the relief of the pain that followed injection of arg. nit. into the deep parts of the urethra, and succeeded by a qualitative change in the urine. Before the deep injections were made a teaspoonful of sod. bicarb. dissolved in a tumblerful of water was injected into the bladder. When the urine was thus rendered artificially alkaline the pain and painful desire to micturate no longer came on after the injections. The idea seems a useful one and deserving of being followed out in the case of other mucous surfaces and secretions.

◆

Austria.

[FROM OUR OWN CORRESPONDENT]

VIENNA, Jan. 12th, 1894.

HERNIA INFLAMMATA.

PROF. ALBERT, in his clinic, reviewed the various forms of hernia that had come under his notice during the last year, wherein he classifies three principal forms, adhesive, exudative, and purulent. Another group of such cases he is inclined to designate hernia inflammata, and produced a woman, æt. 56, to demonstate his views. She first came to him in February, 1889, with a large umbilical hernia of several years' standing. At that time all active phenomena had ceased, although the alimentary canal was still disturbed. The protrusion was as large as the head, the surface irregular and knotty, over all tympanitic, tense, and unyielding. Some of the knots appeared fluctuating, others hard and resisting. The sensation was various: some parts could stand pressure, others very tender. The colour of the skin around the hernia was normal, while over the knots it was reddish brown; one of these prominent fluctuating knobs was reddish blue and very sensitive. The bowels were confined, suffering from eructations and vomiting. The patient becoming worse from a new attack of exudative inflammation in the old protruding hernia, she was put to bed for three weeks, bowels treated with clysters till all the symptoms disappeared, the red parts over the knots becoming light. Shortly after another attack demanded operation. When the fluctuating sac was opened a large quantity of flocculent serous fluid containing hard pieces were emitted. On closer examination the colon was found to be discharging this serous flocculent matter. The wound was washed out and closed, but the vomiting still continued. The woman suddenly died one hour after the operation. The post-mortem examination of the omentum exhibited the appearance of chronic inflammation.

The second case was a man, æt. 63, who had suddenly been attacked with left-side hernia after a short walk five years previous. He often complained of constipation and colic, slight pain and increase of the hernia. On the 23rd December, 1893, after a stool, he was attacked with severe colic, the hernia enlarged and was tender with vomiting. Hockenegg attempted to reduce it, but in vain; it was suddenly reduced by a discharge of wind, followed by copious stools. On the 24th he was perfectly well, but about 5 p.m. the attack was renewed, and singultus supervened, relieved by opium, but vomiting increased. On the 25th singultus renewed, the hernia tense, gurgling and very painful, which induced us to operate. On opening the sac a red part of the bowel protruded, which at first appeared like the colon, but closer examination revealed a distension of the small intestine. After relieving all adhesions half a metre of the omentum was found protruding, hypertrophic surroundings, with inflamed reddening. On the first day after the operation the patient expressed himself perfectly well, but singultus soon followed. In both these cases we have large hernia and years of protrusion with irritation of the omentum. In both cases we have exacerabations with intermitting inflammatory periods. In both the contents were hypertrophied and complicated, resembling an inflamed joint where the capsule is distended and vegetating through mechanical operations even in loose hernia as well as strangulated.

The Bacteriological Institute.

The Hungarian Minister of Agriculture, in conjunction with the Veterinary College, has arranged to devote a certain sum of money to this particular branch of education, confining the investigations to an accurate examination of all infectious diseases respecting habit, history, and life duration of the microbe.

The Operating Theatres.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

Amputation after Ununited Fracture.—Mr. **Edmund Owen** operated on a female infant, about a year old, whose left tibia and fibula had been broken at birth near the junction of the middle and lower thirds. He said that possibly the fracture had for a while passed unrecognised. When the child was admitted into the hospital some months ago, there was no attempt whatever at union, the lower part of the leg and the foot being flail-like. The lower fragment of the tibia was atrophic, and its upper end was somewhat pointed. Soon after admission he had cut down upon the seat of fracture, and having freshened the ends of bone, had adjusted them by a silver wire, and had secured the limb in a permanent and solid dressing. After this the child went on well enough and the wound soundly healed. But unfortunately the fracture eventually turned out as flail-like as ever, and now there was no treatment left but amputation, which he then reluctantly performed. He remarked that ununited fractures in children were of rare occurrence, and all that was known of them would be found in a valuable article on that subject in Sir James Paget's "Studies from Old Case-books." It so happened that this case of ununited fracture was the third on which he had operated recently, and in each instance his treatment had proved ineffectual. One of the other children, he stated was a little boy on whose tibia he had, indeed, twice operated. At the second operation he had had the kind help of Mr. W. G. Spencer, who supplied him with a graft from the diaphysis of the humerus of a puppy, with the idea of stimulating the child's bone and periosteum to form osseous cement; and though, for a time, this child gave excellent promise, the ultimate result had been absolutely disappointing. He hoped, however, to try another operation on that boy before resorting to what seemed to be an inevitable amputation.

ROYAL FREE HOSPITAL.

Operation to Restore the Bridge of the Nose by means of the Breast Bone of a Recently Killed Blackbird.—Mr. **Barrow** operated on a woman, æt. 27, in whom the bridge of the nose had been completely destroyed in consequence of a lift accident some two months ago; the bone had subsequently come away in pieces, as many as twenty-two having been removed. The wound had originally been in the shape of an inverted T, and had been sewn up; after the pieces of bone had come away a great deformity resulted, and the condition interfered very much with the patient's breathing. Mr Barrow commenced by incising the scar at the summit of the T, and next freed the skin and integuments all round the incision, a blackbird was then killed and its breastbone cut out, this, after having been carefully shaped with scissors, was placed in the wound at right angles to the incision, which was then drawn together over it, the bone of the bird taking the place of the bridge of the nose in the patient; the sewing up of the incision took some time and trouble as several of the stitches had to be taken out and the flaps loosened a little more with the knife before being finally brought together, this was in order to avoid all tension. The whole was then freely dusted with iodoform and orders given to apply no dressing but to leave it exposed. Mr. Barrow said he did the operation as an experiment, never having done it before himself nor having heard of its having been performed by any other surgeon. He instanced successful cases of the bone having been replaced in a trephine opening, so he thought it was as well to try and remedy a deformity by taking a piece of bone from a recently killed animal. In the present instance he had selected a bird because he thought the piece of bone utilised was of a convenient shape; there was, he imagined, no other reason for choosing a bird, as any other animal would do just as well; one disadvantage, he pointed out in the bird was, that the corpuscles of the blood were of a different shape to those in the human being, so perhaps there might be less chance for the vitality of the piece of bone after the operation.

ST. GEORGE'S HOSPITAL.

Painful Stump of Three Years' Duration.—Re-amputation.—Nerve Stretching.—Mr. **Bennett** operated on a man, æt. about 40, who had been suffering from acute neuralgic pain connected with the stump of a Syme's amputation performed at another hospital three years ago. The pain had been continuous since that period, and was greatly intensified by pressure over any part of the lower third of the leg, and, on the stump being manipulated, violent spasms were excited throughout the limb, these lasting for half an hour or more. Various anodynes and other medical means had been tried without success, and the patient's health was beginning to fail in consequence of the suffering he endured. It was therefore decided to re-amputate the limb at a higher point although it was by no means certain that this would effect a cure. The re-amputation was performed immediately below the knee-joint, and, with a view to render the chances of cure more probable, each nerve in the stump was seized with pressure forceps and stretched to the utmost extent. Mr. Bennett remarked that the prospects of the case so far as cure was concerned were unfortunately very doubtful, as it was not unlikely that some central changes had occurred in the nervous system which accounted for the pain, although there were no evidences of ataxia, &c. The treatment now adopted he said was therefore only carried out as it seemed right to give the patient the advantage of any chance of recovery, however slight, before resorting to severer methods such as division of the posterior roots of the spinal nerves. He further pointed out that the amputation immediately below the knee was selected in preference to amputation through the knee-joint after Stephen Smith's method, as rapid healing of the stump was regarded as essential, and in the operator's experience the union after Stephen Smith's method was sometimes extremely tedious.

WEDNESDAY, JANUARY 17, 1894.

A BLOW AT NOTIFICATION.

To say that the notification of infectious disease is on its trial is to use one of the commonest phrases of current medical journalism. Nor could one be accused of straying far from the beaten track of commonplace if one were to remark that the various incidents of the encounter are being watched with keen interest alike by friend and foe. There is hardly any modern sanitary law which has excited more determined hostility than the Notification of Infectious Disease Act. At the present moment one is bound to say that the popularity of notification has received a heavy blow at the hands of its own advocates, who in the persons of a London Vestry and its Medical Officer of Health have illustrated one of the most burning objections urged against the Notification Act by its opponents. There can be little doubt that in the main a smooth working of notification can be secured only by a mutual forbearance and co-operation between general practitioners and medical officers of health. On the point of diagnosis especially ought there to be the fullest surrender of individual opinion on the part of the medical officer. An unguarded expression would be likely in many cases to injure the certifying practitioner. So firmly is this standpoint adopted by the profession generally, and also, we had believed, by the sanitary authorities, that it is with something more than an ordinary sense of astonishment and disgust that we read the report of a case which was lately the subject of a magisterial decision in the Clerkenwell Police Court. The facts of this extraordinary affair, as reported in the public prints, are simple. The Vestry of St. Luke's were summoned by a Dr. Evan Jones, of Goswell Road, for the non-payment of a fee of half-a-crown. It appears that in July last the plaintiff formally notified the Vestry of the existence of a case of erysipelas occurring in his practice. At the end of the year he sent in an account, and was surprised a little latter by having his list returned to him with the brief but pointed marginal note "not erysipelas" opposite the case in question. At the same time the Vestry declined to pay the fee, and the consequent discussion at one of its meetings was said to have reflected seriously upon the character of Dr. Jones. The medical officer supported his contention in court that the disease was not erysipelas. To endorse that view a medical man was brought from the West End to give his views upon the subject. This gentlemen is described as a "specialist in erysipelas," a title which must fail to present any definite position to the ordinary comprehension. Surely the recognition of erysipelas should be a part of the most elementary education in medical matters. This specialist, moreover, had never seen the case. His opinion therefore, was derived from hearsay only, and his evidence correspondingly worthless. Why he was chosen and brought into court on such an errand at the expense of the ratepayers is a question that the public press might take up with advantage. His presence in Court had the practical effect of backing up the medical officer in questioning the diagnosis of a medical man simply and solely on a petty difference of opinion. We are glad to say that the magistrates, after due consideration of the facts of the case, came to the conclusion that Dr. Jones had granted the certificate in perfectly good faith, and was, therefore, entitled to his fee. Now this case raises issues of great importance to medical practitioners. Into the vexed question of diagnosis it will be of little profit to enter. Everyone who has any extended experience in practice is aware that there are many borderland cases in which it is for some time difficult or impossible to diagnose with confidence the existence of erysipelas. In typical cases no such difficulty exists: it would be recognised at a glance by a first year's student. When we come to obscurer cases, however, we have no hesitation whatever in recording our conviction that a general practitioner is far more likely to be right than the Medical Officer of Health. The latter misses the practical bedside training that is absolutely essential to an adequate knowledge of the appearances of disease. He is likely to become scholastic, and to frame his opinion on book symptoms. He knows nothing of the marvellous faculty of diagnosis possessed by some men, which at first sight appears intuitive, but which is really the result of patient study and observation. At the best a diagnosis in a very doubtful case may be regarded as a purely tentative view founded on a summing up of probabilities. Such a diagnosis is always open to question, and certainly does not fall within the matters of fact on which a police magistrate may be called to give a decision. The result of the St. Luke's case is of much importance because of the valuable precedent which it has established as to the rights of general practitioners to maintain their own opinion in spite of the contrary statements of medical officials. The next step required for the consolidation of those rights will be to bring an action for libel against some over-zealous medical officer who has publicly questioned the diagnosis of a medical man in his district. In such a case it would not be difficult, one would imagine, to prove damage to reputation. Whatever may be the ultimate issue of these unfortunate differences, few will deny that such ill-advised acts as those of the St. Luke's Vestry are likely to irretrievably damage the cause of notification, but they may draw together the true friends of sanitary progress to take counsel betimes.

◆

LUNACY ADMINISTRATION IN AMERICA.

WE had occasion some months ago to indicate with a force of language which subsequent events have justified the iniquitous and cruel policy of the Lunacy Commission of the State of New York. It is a question of men and motives, and the average citizen needs no expert evidence to guide him in getting to the bottom of the matter. The facts are plain business facts, that may be called jury facts, and if the average intelligence of the State of New York is not competent to come to a sound jury decision on the matter we are much mistaken. It seems incredible that in this *fin de siècle* age, the State of New York, of all places on earth, should be completely at the mercy of three men in respect of its lunacy administration. One can scarcely conceive it possible that these three Commissioners have legally vested authority to control the commissariat of the eight State hospitals for the insane directly from headquarters, that the Managing Boards of these hospitals may submit schedules of requirements to the Central Board, but cannot contract for or order supplies for their own asylums. These institutions have been hampered and harassed in their work by the pettifogging practices of the Lunacy Commission. In one asylum the patients were deprived of oatmeal for a month because of failure to specify the particular brand desired, though quality and price were mentioned. Striking out requests for nails, timber, lime and bricks had stopped necessary repairs. In another case the complaint is, "We have gone weeks without tea, and then got permission to buy 2 lbs." &c. A conference of Asylum Managers and Superintendents at New York revealed these and other delinquencies of the Lunacy Commission. Numerous instances were given of the positive hardships suffered by the insane in the New York State Asylums, and to cut off the supply of tobacco is but one of many illustrations of the scandalous excisions perpetrated by the red-tape machinery of the headquarters at Albany. It might be supposed that a committee of three would be practically unanimous in working out its self-concerted scheme of economic reform, but it is not so, and though there might be some hope of playing one commissioner against another, in actual practice it does not work to the advantage of the asylums. For example, pipes, valves, fittings, &c., estimated for by direction of Dr. Macdonald, the Medical Commissioner, were disallowed by the Commission of which he is Chairman. An item for hoppers, disallowed, was an estimate for a special kind recommended by Commissioner Brown. Dealing next with the machinery of asylum administration, this absolute and arbitrary Board tries to reduce the strength of the staff, on the principle that insane labour is as good and reliable as sane labour. If an insane person can do without supervision, and can labour to maintain himself, why should he be kept in a State hospital? Why does this cheeseparing Commission not take a broad statesmanlike view of the matter, and shut out from asylum care the men who can apparently work for a living outside in the world at large? They ought to see the end from the beginning, and face the logical result of the fiscal policy and principles which they now enunciate. This Commission would have the patients make the soap, wash the clothes, mend them, herd pigs, do all the farm work, and in short, to use an American phrase, "run the machine" themselves. Did ever a more preposterous idea originate outside an asylum before, either in America or elsewhere?

Now, it may be asked, what is the composition of this remarkable Commission, what is its authority, and what are its duties? It is, as already stated, a committee of three, one medical man, with very little medical spirit or sympathy for the true wants of the insane, and two laymen. The authority of this Commission is absolute, and the history of its present position may be quoted from the *New York Medical Record*:—"Though the projectors of the law creating the Lunacy Commission of this State were governed by the conservative opinions which have made lunacy administration so successful in England, the Commission created by the law was from the first inspired with the idea that reforms in the management of the hospitals could not be effected through the local boards, by friendly advice and assistance, but must be accomplished by its own assumption of executive powers. Instead of making an exhaustive examination of all the institutions in order to discover defects of management, and attempt to remedy them by advice and friendly co-operation, the first notable act of the Commission was to secure an amendment of the entire law. There are three noticeable features in the amended law: (1) The salaries of the Commissioners, already liberal, were considerably raised; (2) The regular and systematic visitation of hospitals—made statutory in the English Act—were made discretionary, the reason of this change, as given by the Commission, being that the individual Commissioners had not the physical ability to make the required visits; (3) A much more simple and direct method of enforcing the orders of the Commission upon the hospital management." We need not quote further. This arm-chair Commission is a political machine, and a disgrace to the premier State of a great Republic. It utterly and ungraciously ignores all local authorities and all local considerations. It has degraded one of the noblest and most humane functions of the State—the care and hospital treatment of the insane—to the level of Profit and Loss accounting. Such a Commission has no *raison d'être*, it belongs rather to the Middle Ages, and we are sure of this, that outside the political machine of which it is a part, and which, if a healthy organism, would have ejected it long ago, there can be no true sympathy with this treatment of asylums for the insane among the people of the State of New York. It is one of the inconsistencies of a country which is the home of local government that such absolute and arbitrary centralisation of power should exist. What would be thought of the English Commissioners projecting and carrying a complete Lunacy Act in Parliament and superintending feeding, clothing, and physicing all the English asylums direct from their office at Whitehall. Compare the relation of the Scotch Commissioners with asylum superintendents as it is so favourably and justly described by Dr. Clouston in the October number of the *American Journal of Insanity* with the state of matters in New York. All interested in the well-being of the insane must sympathise with the Boards of Management and the Medical Officers of the New York hospitals for the insane. They have thrown down the gauntlet. They are backed up by the medical press of New York and Boston, and a long and severe struggle must ensue to have the present lunacy law cancelled, and a new and more enlightened one to take its place. For the sake of the unfortunate insane, and for the credit of New York heads and hearts, we hope this end will be soon accomplished.

◆

PRIORITY IN THE USE OF ANÆSTHETICS.

Fresh interest has been aroused in this subject by a paper in *The Century* magazine by Miss Simpson, daughter of the late Sir James Simpson. It is quite natural that the authoress should claim the fullest credit for her distinguished father's priority of discovery of the anæsthetic effects of chloroform. That she should be unfamiliar with the fact that anæsthetics were, in some form or other, known and used in surgery from the earliest ages is a curious fact. Few men did so much to trace the use of pain-nullifiers in surgery as the late Sir James Simpson, and his book on the History of Anæsthetics, published in 1871, is still read. The duty of recalling to professional readers the fact that chloroform was the discovery of Guthrie, of Brimfield, Mass., in 1831, and was first used by Ives, of New Haven, in 1832, as an anæsthetic, and was extensively used as a flavouring agent in Great Britain at the time Sir James Simpson first used it, is under the circumstances not a pleasant one. That a young student of medicine should be horrified on seeing a major operation, and at the moment resolve to give up the study of medicine, is not an unusual experience. The majority of our readers have had similar experience in surgery. Simpson has the credit of popularising the use of anæsthetics, but it is a remarkable fact that at the time he was being horrified by Liston's operation ether was being freely used as an anæsthetic, having been introduced into practice by Dr. Long, of Jefferson, Georgia, in March, 1842. The operation was the subject of an exhaustive article in the *Virginia Medical Journal* for May, 1877, by Marion Sims, in which he told the story of the introduction of anæsthesia as told to him by Dr. Wilbite, of Anderson. S. Carolina, who had been a pupil of Long's. In the discovery of oxygen by Priestley we have the genesis of modern anæsthesia, as Mr. Foy has shown in his well-known book on anæsthesia. The name of Sir James Simpson will always be honoured in Medicine; he did much to advance the science, but it is injudicious for his friends to put forward claims on his behalf to honours to which he is in no way entitled. Modern anæsthetics are the direct outcome of Dr. Beddoe's practice of pneumatic medicine by "factitious airs," and it was Beddoes who first experienced the anæsthetic effects of nitrous oxide gas, and soon afterwards he learned from Pearson, of Birmingham, that the vapours of sulphuric ether inhaled had a similar effect in deadening pain. Curiously enough Davy's name is still closely associated with the discovery of the anæsthetic effects of nitrous oxide gas, and Beddoes is comparatively unknown; few know anything of Pearson's letter on the anæsthesia of ether. Long, who first etherised in surgery, is not given the honour due to him; and by reiteration year after year Simpson's friends have persuaded the public and almost the medical profession that he is the discoverer of anæsthesia. It is against this we protest. Simpson was too great a man to desire to decorate himself with borrowed plumes. Granting him all the honour, and it is much, that he won, we nevertheless in honour of the mighty dead refuse to be silent when their works are being filched to enhance the reputation of others. Truth will in time prevail, and Priestley, Beddoes, Pearson, Guthrie, and Long will ultimately be honoured.

◆

Notes on Current Topics.

The Council of the Royal College of Surgeons and the Privileges of the Fellows.

The Report of the Committee of the Council of the College of Surgeons on the question of the regular meetings of the Fellows was considered at the quarterly meeting of the Council on the 11th inst. The report was to the effect that the meetings in question shall be for consultative purposes only, without having any official or corporate character efficacy; that the meetings shall be summoned by the Council at such times and for such objects as may by the Council be thought desirable, either with or without a requisition from the Fellows; that such requisition must be signed by at least thirty Fellows, and contain a statement of the objects for which the meeting is requested; that two meetings shall be held in each year on the following days, viz., the first Thursday in July and the first Thursday in January; that the subjects to be considered shall be (*a*) matters referred to the meetings by the Council, (*b*) motions introduced by Fellows; that the motions introduced by Fellows shall be signed by the mover, or by the mover and other Fellows, and must be deposited with the Secretary not less than twenty-one days before the meeting; that the President shall determine what motions are in order, and direct the arrangement of the agenda; that the quorum of each meeting shall be thirty, and if at the expiration of fifteen minutes from the hour for which the meeting has been summoned a quorum be not present, the meeting shall not take place; that if after the commencement of the meeting it shall be found upon a count that a quorum be not present the meeting shall be dissolved; that the President or one of the Vice-Presidents, or in their absence the senior member of the Council present, shall be chairman of the meeting, and the chairman's decision shall be final upon all points of order which may arise; that the secretary of the College act as secretary to the meetings and transact all the business in connection therewith. All these recommendations the Council have adopted, and the Fellows of the College will now be in a position to judge of the extent to which their status in College affairs has been improved by these concessions. We shall refer more fully to this subject in a future number.

The late Sir Andrew Clark and Consultants' Fees.

In the current number of the *Strand Magazine* is published an illustrated article concerning the late Sir Andrew Clark, with views of his grave at Essendon, Camfield House, his house in Cavendish Square, of the London Hospital, and others, and in addition an excellent likeness of his eldest son, Surgeon-Lieutenant-Colonel Sir James Clark, the present baronet. The article contains nothing very striking to medical readers, although doubtless the reference made to Sir Andrew and his fees will come somewhat as a surprise to many. The writer says that with respect to fees, Sir Andrew always took what was offered; sometimes he would receive £5,000 for a long journey, sometimes two guineas. For example, after a hard day's work he was urgently summoned to a place one hundred and twenty miles from London. It was a very wet night. There was no carriage to meet him; no fly to be had. After walking a mile or two he arrived at a small farm, and found the daughter suffering from an attack of hysteria. Sir Andrew did what he could, and evidently gave satisfaction, for when he left the mother said, "Well, Sir Andrew, you have been so kind that we must make it double," and handed him two guineas. He thanked them and said "Good-bye." The writer further says that Sir Andrew would never hear of charging more than his usual fee because a person happened to be rich. On one occasion, being in the country, he was asked to see a very rich patient, who was prepared to pay him his full fee from town, but as he informed the medical man that he had not come from London, Sir Andrew would only claim a third of the usual fee. Still he was not indifferent to fees, on the contrary, he rather took a pride in telling how much he earned. He is said once to have received £5,000 for going to Cannes. From Anglican and Roman Catholic clergy, sisters, nuns, and all engaged in any charitable work (unless rich men) he never would consent to receive a fee.

An Undesirable Practice.

Not long since we had occasion to animadvert on the persistency with which a whilom humorous contemporary sought to advertise a certain physician, thus affording incontestable evidence that someone on the staff had—to use Mr. Labouchere's expression—been "got at" by the physician himself or by some over-zealous friend. We are now constrained to believe that Mr. Labouchere himself has been "got at" in the same way, judging from the fact that scarcely a number of his magazine is issued which does not mention the name and speciality of a certain practitioner who is a "specialist on obesity." Whether this is a small token of gratitude for services rendered we cannot undertake to say, in ignorance of the corporeal tendencies of the editor of *Truth* and his major staff. In any event he does his *protégé* sorry service by this injudicious method of touting.

The Tyson Drink Cure.

It will be recollected that a few weeks ago we called attention to an attempt which was being made, under the auspices of certain temperance workers, to exploit this substitute for the nearly defunct Keeley cure in Dublin. The dodge was to get up a committee of inquiry as to the merits of the nostrum, and when, as anticipated, it reported eulogistically, to publish the report far and wide. The enterprise, in consequence of our explanations, failed in Dublin, but we note that the same method is being pursued in the other large towns, notably in Scotland. In Dundee it was recently tried on, when an agent from the Tyson Company came down from London to work up the inquiry. Unfortunately, however, he was anticipated by a report from the *Chemist and Druggist* of a prosecution of the Company in Australia for selling poisons. A patient had died suddenly after taking the "cure," and, though it had been decided the "cure" was not to blame, an analysis had been produced in court from which it appeared that the stuff, largely advertised as "purely vegetable and harmless," contained a large quantity of strychnia. The analyst assayed the value of the medicine which was sold at £10 10s. at 2s., and the judge gave a decree for £5 5s. fine and £10 10s. expenses. This revelation disposed of the chances of the Commission of Inquiry as far as Dundee was concerned, and as reported by our Scotch correspondent last week, ex-Provost Hunter vacated the chair in disgust at the meeting held to promote the "cure." Nevertheless, a show was got up, and 17 irreclaimables were invited, of whom only 6 turned up. They each got a bottle of medicine and a box of pills, and took a dose of each then and there. We are surprised to observe that none of them have yet announced their perfect cure: this generally followed after the first dose as a matter of course.

Poisoning Made Easy.

The London papers observe, with good reason, upon the fact that a servant girl who poisoned herself with strychnia experienced no difficulty at all in getting the drug from an oilman, though she would have found it impossible to get it from a qualified pharmaceutist or druggist without a doctor's order. The fact is so, for under our laws an oilman is subject to no limitation or penalty such as is imposed upon the more regular and better-educated trader. This law is a specimen of several of our statutes, like the Compulsory Notification Acts, which restrict and punish regular practitioners, but leave it perfectly open to irregulars to do as they like. Classes (for instance, nurses and plumbers) who aspire to the distinction of State recognition ought to recollect that if they get what they want the boon will necessarily be accompanied with rigid limitations upon their freedom of money-earning by their trade, while other persons who do not ask for such recognition can continue the same business without any restriction whatever, and can thus beat in life-competition those who are bound down by registration.

The Medical Practitioners' Association.

The Medical Practitioners' Association had a meeting last week at the house of the President, Dr. F. H. Alderson, at Hammersmith, which was largely attended. The reunion was for the purpose of hearing a paper on the subject of "Medical Clubs" by Dr. Johnstone. The reader strongly urged the necessity of establishing medical clubs for the working classes, and drew attention to the advantages to be derived by the medical officer being allowed to discharge his duties unfettered by a committee. A long discussion arose in respect to the various important points to which reference was made in the paper, and in the end the following resolution was unanimously carried: "That this meeting considers that district associations for the medical care of the working classes are desirable, and that a committee of the Medical Practitioners' Association be appointed to consider the matter with a view to carrying it out." The committee was then appointed, and a vote of thanks to the reader of the paper, as well as to Dr. Alderson for presiding, brought the business of the meeting to an end.

Epidemic Disease on Board H.M.S. "Howe."

The *Howe* has not proved a healthy ship since her accident. It will be remembered that last year she ran on some rocks at the entrance to Ferol Harbour, where she lay for months partially submerged. After being brought to England and repaired, she was again placed in commission, and at present this fine battleship is on duty at Malta. However, a great deal of sickness has since her re-commission taken place on board, mainly in the form of an epidemic throat disorder, the precise nature of which has so far not been definitely explained. The naval authorities seem to have become fully alive to the seriousness of the condition of affairs, and it has consequently been decided to renew the whole of the *Howe's* woodwork, the impression being that owing to the long immersion at the time of the accident the wood now gives off foul emanations which have been the cause of the illness among the crew. Surely this proposition is somewhat radical in its nature if the real cause be as that stated. Has everything been done in the way of disinfection? and what reasons are there for supposing that the woodwork especially is at fault? Quite possibly the whole ship requires nothing more than thoroughly disinfecting, which the Admiralty would do well to try, if they have not already done so, before proceeding to expensive works of alteration.

Registrar-General's Weekly Returns.

The returns of Sir Brydges Henniker are now founded on a new estimate. The populations of the thirty-three great centres of industry are now calculated prospectively. For the week ending 6th January, influenza shows a decrease, and also small-pox, although the latter is still raging in Birmingham. Diphtheria has killed 89 persons, as compared with 107 in the preceding week. More than two-thirds of the fatal cases were registered in London. In the "inner ring" of London the deaths from influenza numbered 87, as compared with 164, 147, 108 for the three preceding weeks. The Metropolitan Asylums Board had 2,855 scarlet fever patients as against 3,102, 2,993, and 2,988 on previous Saturdays. No less than 15 infants under one year of age were smothered by suffocation in bed in Inner London alone. In the "outer ring" 8 deaths from measles, 5 from scarlatina, 13 from diphtheria, 22 from whooping-cough, and 5 from "fever" were recorded.

Damp Cellars.

The fact is often overlooked that a damp cellar in a house is a very serious drawback to the healthiness of the residence. Strictly speaking, after the drains, nothing is more important than to ascertain the condition of the cellar. For the most part, architects are content to pay little or no attention to the sanitary principles which should guide them in its construction. If a cellar be damp it is the last place in which food should be kept. The moist air is so favourable to the growth of the micro-organisms of putrefaction that the food is apt soon to become contaminated: moulds grow most luxuriantly, milk turns sour with every thunderstorm, fruit will not keep, and the cook finds herself continually obliged to throw away decayed vegetables. But all the emanations, foul and otherwise, generated in a damp cellar are always certain to pass into the house, owing to the higher temperature of air in the latter. This, of course, means that the inmates must suffer—so much so, that cases of indefinable malaise have been recorded in this connection in which the symptoms caused suspicions that it was the drains hich were at fault. Practically, most cellars are nothing more than a hole, equivalent to a shallow well. There is seldom any provision made for ventilation, and thus from week to week the air contained in the "hole" remains unchanged, and ultimately finds its way into the house.

Lunatics in Workhouses.

Stimulated by a correspondent, the *Irish News* reprimands a coroner for going out of his way in commending the lunatic department of an Irish Workhouse. By a recent order of the Local Government Board, inquests may be held on the insane who die in workhouses. This was the occasion of the coroner's offence against those who are anxious to see lunatics confined in asylums only. A new asylum is necessary, and naturally there is a strong feeling in the Corporation, and an inclination to avoid the expense if Workhouses can meet the requirements and provide for supplementary and harmless lunacy. The question is one which can best be decided by the Government Inspectors and the local authority working harmoniously.

Asylum Abuses—the Old Story.

A correspondence calculated to inflame public sentiment and disparage the justice and humanity of asylum committal and treatment has been inaugurated with the New Year by the *Echo* newspaper, which has an unenviable reputation for its anti-everything proclivities. "One swallow does not make a summer," nor does one case of misadventure justify the spreading of a public *fama* against asylums generally. We cannot vouch for the facts, but an accusation is made against the Lewisham Workhouse, and some person or persons whose names are not published, to the effect that the complainant was sent to Canehill Asylum, and the medical superintendent failed to detect the slightest sign of insanity, so that the individual was discharged within a month, after being brought before the Committee. (In a Scotch Asylum, the patient if found not insane would be discharged at once.) The result of this letter is the appearance of others containing the usual catalogue of grievances. It is a somewhat curious fact that asylum officials rarely receive any kindly words of acknowledgment from patients discharged recovered, and men and women who have been insane and have afterwards done their work in the world well for years may, and not in a few instances do, retain a grudge against the asylum and all concerned. It may be a symptom of the insane diathesis which can never be wiped out, though the patient is cured of his insanity, and the fact that this diathesis exists in the great majority of the patients who have been discharged recovered should make journalists careful not to lend an ear too readily to tales of asylum abuse and ill-treatment.

The Tuberculosis Report.

Still this much-longed-for report hangs fire, and the date of its probable appearance cannot be even approximately fixed. This delay, we hear, is due solely to the fact that Dr. Sims Woodhead, who had undertaken to carry through an important series of observations, is unconscionably behindhand in communicating his results to the Commissioners. We are, of course aware that Dr. Woodhead is a very hard-worked man, but we hope that if the delay be entirely his, he will do his best to expedite matters and set this vexed question at rest, or as nearly at rest as present knowledge and means of investigation will admit of.

Self-destruction Aided by Science.

It matters not in what manner persons bent on suicide proceed to this purpose, the end is the same, namely, self-destruction. The uneducated are satisfied to resort to the common methods of carrying the act into execution, such as hanging, poisons, bullet wounds with firearms, and so forth. But the case is very different when, as it occasionally unhappily occurs, members of the medical profession place themselves in the same category with unreasonable beings who purposely destroy themselves for some imaginary grievance or trouble. Not always, however, can it be said that these suicidal acts are committed by persons who can be held to be responsible for what they do, and especially is this the case when any declension of the moral nature has followed the habitual abuse of some powerful drug. Charitably, we would be disposed to adopt this latter view in the case of a sad, though desperate, suicide of a promising young medical man in Berlin last week. He was addicted to the morphine habit, and being about to become engaged, he became despondent at ever being able to leave off the habit. Resolving, therefore, to destroy himself, he effected his purpose, so the newspaper report runs, by opening all the principal arteries in his head, neck, hands, and feet, making altogether fourteen incisions. Even if for "arteries" one reads "veins," the determined nature of the act would still show that very little reason could have been left in him with which to realise his position. He was found "swimming" in blood, and on a table near was found a bottle half full of morphia, together with a note stating the time at which the last dose of the drug had been taken.

"St. John's Hospital in 1894."

Under the above heading *Truth* testifies to the reformed system of finance and general management now in vogue at St. John's Hospital. The editor of that journal had been appealed to last year by a number of people who were anxious to know whether the present arrangements of the hospital were such as to entitle it to the confidence of the charitably disposed. The same gentleman, as readers will remember, attacked the management in 1888 and 1889, and in the libel actions that ensued the existence of serious financial irregularities was admitted. After personal investigation, Mr. Labouchere has arrived at the conclusion that "subscribers now have as good security for the proper application of the funds they contribute as they can have in any charitable undertaking." At the same time he states explicitly that he does not withdraw opinions previously expressed upon past occurrences at the hospital. There can be no doubt that the enterprise of a lay journal has been the means of bringing to a termination what was, to say the least of it, an unsatisfactory system of management in this hospital, which has for many years past been the subject of more or less recurrent scandal. These and similar affairs simply emphasise the need of a central control of medical charities not only in London, but also in provincial towns.

Hydrophobia.

We have many times endeavoured to make manifest to our readers that rabies is, notwithstanding the occasional recrudescence of a craze about it, so scarce a disease as to be almost unknown and, therefore, that the elaborate laws for the muzzling of dogs are monuments of stupidity and ignorance. In the record of the work done in the month of November last by the Pasteur Institute in Paris, we find additional proofs of our contention. It is reported that, within the month, 129 patients were treated in the Institute, of whom none died. This would, indeed, be an incredible record of success but for the context, from which it appears that in only 5 out of the total number was the animal from which the bite was proved, by experiment, to be rabic. In all the others the only evidence of the fact was the certificate of a veterinarian, a policeman, or of the patient himself. We do not at all desire to discredit Pasteurism. Quite the contrary. Assuming that even two out of the five patients (out of 129) bitten by animals proved to have been mad had received the infection, Pasteur has done much if he saved the lives of these two by his inoculation. Our object is to show how truly ridiculous is the action of Government departments and Boards of Guardians who decree the muzzling of all dogs for no better reason than that 5 persons out of 129 have been bitten by dogs proved to have been mad. As for the other 124 we say that we do not attach the slightest confidence to the statements of policemen, veterinarians, or patients, and that we do not believe that even 1 per cent. of the animals stated to have inflicted bites were rabic. But surely, if the muzzling is to be effective it should be universal, and we shall be amused to see the effort of Mr. H. Gardner, M.P., and his department to muzzle 17 cats, a horse, a sheep, and a pig, all of which were returned to M. Pasteur as the centres of the infection.

The National Leprosy Fund.

Practically speaking, this Fund has now been dissolved, and out of its remains has arisen a small committee consisting of Sir Joseph Fayrer, Sir Guyer Hunter, and Mr. Jonathan Hutchinson, to whom have been handed the balance remaining from the Fund, amounting to upwards of £500, to expend as they may deem best in promoting further investigations into the nature and causes of leprosy. Apparently the idea is to offer honoraria of 50 guineas for papers on certain subjects in connection with the disease. Without, however, agreeing with this plan, which seems to have been decided on, we should like to know what is intended to be done with these papers after they have been written, and the prizes, if any, awarded. Before this scheme was thought of, we believe that a prevalent feeling in the defunct committee was that the money should be expended in bringing out further numbers of the *Leprosy Journal*. This publication, of which four parts have been issued, has proved to be a most valuable storehouse of leprosy literature, and regret can only be felt that the decision should have been arrived at to discontinue it. More especially is this the case, because of the loyal support which the *Journal* received throughout the world from all the best known and able writers and authorities on the subject with which the *Journal* exclusively dealt. It became at once the medium in which the workers on leprosy were glad to record their opinions and experience, and the high standard of the contributions was a sufficient proof of its scientific value. We must express a doubt whether it will be found that the leading leprologists will take kindly to the idea of being asked to compete for prizes by contributing papers on the subject which they have made their own. In all probability they will rightly hold that it would be *infra dig.* to do any such thing, whereas we may reasonably conclude that there would be no difficulty in getting them to contribute to the *Leprosy Journal*, carried on under the same auspices as before.

Physiciancy of the City of Dublin Hospital.

We understand that the physiciancy of this hospital has become vacant by the resignation of Dr. Hawtrey Benson, who succeeded his distinguished father Professor Charles Benson, in this office 17 years ago, and has since been a favourite teacher in the hospital. Dr. Benson, we are glad to know, retires for no other reason than a desire to devote himself solely to private practice. Mr. Broomfield, assistant physician to the hospital, will, we understand, be a candidate for the position, and we have not yet heard that any other competitor has entered the lists. Mr. Broomfield has served the hospital for several years as junior on the physicians' staff, and is certainly entitled to promotion to the physiciancy unless some candidate of special merit presents himself. He is known to be a very competent teacher and an industrious physician.

A Peculiar Gunshot Fatality.

Mr. Elliott, of Aughamillar, near Derrygonnelly, in the co. Fermanagh, lost his life last week by an unusual gun accident. He was cleaning the outside of the barrels of a muzzle-loading gun which was loaded and capped, when he let it fall, and the cap striking against a stone, the charge exploded and lodged in his thigh, blowing away the lower part of the femur and entering the joint. Dr. Kennedy, of Derrygonnelly, was on the spot within an hour, and Drs. Walsh and Gunning, of Enniskillen, afterwards, and the limb was amputated, but, as might be expected, Mr. Elliott died of shock and loss of blood.

The third International Congress of Hydrology and Climatology will be held in Rome on March 29th next, at the same time as the International Medical Congress

Latest Arrangements for the International Medical Congress at Rome.

We are officially informed that in order to meet the convenience of members and their friends accompanying them on the journey to Rome, the Central Committee of the Congress has officially deputed Messrs. Thomas Cook and Son to provide for their accommodation at Rome, and to organise excursions at Rome, at Naples, and to Sicily. Messrs. Cook will charge exceptionally reduced fares for the excursions, and in addition to their regular agents in Rome and Naples, they will send a competent *employé* from London to attend to the arrangements.

Very good hotel and pension accommodation in Rome before, during, and after the meeting will be provided at from 12.50 fr. upwards per day for each person, comprising bed, food, service, and candles.

Excursions from Naples to Vesuvius, Pompeii, Capri, Sorrento, Castellamare, and Baiae for three days, including lodging, food, boats, carriages, and guide, will cost about 70 fr. Excursions to Sicily, ten days, with the following itinerary: Naples, Messina, Taormina, Catania, Girgento Siracus, Palermo, and Naples, including steamers, railways, carriages, guides, boats, and full hotel accommodation, about 280 fr. These prices include 1st class railway fares and hotel accommodation; 2nd class railway fares will be arranged for those who wish it. Intending participators in these excursions should apply at their earliest convenience to the nearest Cook's agency, if possible on or before February 15th next. A programme with full particulars will be appended to the instructions for the journey issued by the Central Committee and forwarded to all enrolled members.

For instructions, cards of identification for the journey at reduced fares, and programmes, application should be directed to the Secretary-General, XI. International Medical Congress, Genoa, Italy.

The great Annie Ruppert has again suffered a fine of £5 and costs for selling her solution of corrosive sublimate as a face wash. This time she made, practically, no defence, but pleaded that her agent had supplied, in mistake, a bottle of the original wash which contained the mercuric chloride instead of her new concoction which is innocent of this drug. The letters, produced did not, however, sustain this plea, but rather showed that she was still trying to carry on the trade, which is very foolish, considering that the people who buy the stuff will buy it just as readily if it contained only sugar and water.

The Local Government Board has sanctioned the borrowing of £2,000 for the erection of an infectious diseases hospital for Rhyl and district at Towyn, Abergele.

The Socialists in the German Reichstag have framed a bill abolishing compulsory vaccination in Germany.

A Cottage Hospital is to be erected at Crewe on ground given by the London and North-Western Railway Company. Mr. F. W. Webb, chief mechanical engineer at Crewe, has promised £1,000, and two further sums of £1,000 each are promised towards its erection. The trustees of the late Alderman Heath have also expressed their willingness to give £650 to the same object.

The mother of a girl employed as a servant at the Fever Hospital, Edinburgh, has made a claim for damages upon the City on account of the death of her daughter, who was accidentally poisoned by one of the nurses at the hospital

In Newcastle, on the 12th inst., two young women, each 19 years of age, domestic servants, living in different parts of the city, committed suicide by drinking carbolic acid, owing to disappointment in love.

A death from an overdose of "bromida" has taken place at the North Kensington Infirmary, but it was not the fault of the drug. A nurse, by mischance, gave twice the prescribed dose.

On the occasion of his 71st birthday M. Pasteur was presented by the Association of Students in Paris with a large silver medal, inscribed as follow: "Presented to M. Pasteur, President of the Association of Students, December 27th, 1893."

Inspector-General of Hospitals E. T. Mortimer R.N., who has just been placed on the retired list, has been succeeded at Haslar Hospital by Inspector-General Duncan Hilston.

The Paris Faculty of Medicine has started a movement to raise a memorial to perpetuate the memory of the deceased distinguished neurologist, Prof. Charcot.

The George Henry Lewes Scholarship in Animal Physiology, tenable for three years, has been awarded to Mr. John W. Pickering.

The names of Dr. W. Gibson Bott and Dr. W. Job Collins have been placed upon the Commission of the Peace for the County of London.

Mr. J. W. Hulke, F.R.S., President of the Royal College of Surgeons, England, has undertaken to deliver the Hunterian Oration at the College in February, 1895.

Professor Virchow has been ill with a severe attack of influenza, but is now making favourable progress.

At the University of Moscow the fees for the curriculum for five years amount to only £80.

Scotland.

[From our own Correspondents.]

Edinburgh University.—From the Annual Report of this University we extract the following figures:—The total number of medical students attending last year was 1,641, 666 (41 per cent.) of whom belonged to Scotland; 557 (34 per cent.) to England and Wales, 74 to Ireland, 79 to India, 229 (14 per cent.) to British Colonies, and 36 to foreigh countries. The degree of M.D. was conferred on 60 candidates, that of M.B., C.M. on 277. The handsome bequest of £5,000 by the late Mr. A. L. Bruce to assist in the foundation of a Chair of Public Health is intimated.

Royal Edinburgh Infirmary.—Last week the two members of the staff appointed by the College of Surgeons as its representatives on the Managing Board took their seats, it is said, under protest from the other members of the Board. Although in many hospitals the acting staff is directly represented on the management, yet in Edinburgh this has never been so, members of the honorary staff having been considered preferable. It has been thought, and is still the opinion in many quarters, that the fact of colleagues being at the same time masters might lead on occasion to some bad feeling, especially if any provisional arrangement as to prolongation of the period of service such as recently came before the Board were again to be brought forward; and again it is pointed out, that if the staff themselves had the right to elect two of their number on the Board to directly represent them, it would not be so bad, but for the members of an outside college, who know that it is against the unwritten rule, to elect two members of the staff as managers seems wrong. Are they to represent their college or the staff? If the staff, what members of it? It is open to the managers to take the drastic step when the annual appointment on the acting staff of the two new managers comes up for ratification to deprive them of their posts. Another reason for the appointment, however, has been suggested. The College of Surgeons as a body is notoriously antagonistic to the women. Its last representatives, who had not served their full time, were thought to be too forbearing to the sex. Two members had to be appointed, strongly anti-feminine, to stiffen the board; the two strongest happened to be members of the staff. *Voilà tout!*

Whooping-Cough in Dundee.—The Medical Officer of Health for Dundee, in his last report regarding the health of the city, refers specially to whooping-cough. He states there were 40 cases of whooping-cough reported during December, and within the same month the disease caused 35 deaths. The obvious inference was that only a small fraction of the cases were reported. Whooping-cough was not included in the list of infectious diseases notifiable under the Act 1882, and therefore the duty of reporting devolved upon the householder alone. In view of the manner in which the householder evaded that duty, it was quite clear that notification by the householder alone, whether voluntary or by statute, was practically worthless.

Correspondence.

HYSTERECTOMY BY THE CLAMP OPERATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Mr. Tait's objections to the operation I use and recommend are so purely hypothetical, and the dangers he appears to apprehend have been shown by experience to be so groundless, that I cannot but think his supposed acquaintance with the operation is more imaginary than real.

The peritoneum included in the clamp separates with the rest of the included stump, and therefore the peritoneum is finally divided at a somewhat lower level than in the usual operation of hysterectomy, and there is nothing to prevent the (granulation) union of muscle with muscle, or tendon with tendon, and skin with skin.

The accurate closure of the peritoneum, which Dr. Bantock and Mr. Tait endeavour to obtain by the use of a single stitch, I obtain absolutely by the wire of the clamp, and there can be no doubt, as Mr. Tait himself suggests, that the perfection of closure is the secret of success. No suture below the clamp is necessary when my practice is followed, and this is a decided advantage, as a suture in this situation is occasionally a source of danger from hæmorrhage.

Less than two years ago (in 1892), when writing our Hospital Medical Report for 1891, Mr. Tait said: "The most serious operation of all those which are performed at this hospital is that for the removal of uterine tumours, technically known as hysterectomy. Since 1879, 48 of these cases have been performed with 20 deaths, giving a mortality percentage of 41·6, a result so disastrous that the operation has been practically given up, only 3 having been performed during the years 1889, 1890, and 1891."

Since this date, and Mr. Tait's retirement from the acting staff of the hospital, some six or seven of these operations have been performed, nearly all of them by my method, and all have been successful. So far there has been no sign of hernia in any case.

I am to some extent concerned about the question of priority. Every surgeon who thinks he has found a good thing likes to have the credit that is just. I have carefully searched all generally available literature and failed to find any description of an operation containing the essentials of my method. I have also asked my friends to do the same with similar result. When a clearer reference than Mr. Tait's is given me I shall be pleased to investigate it.

The method of operation I have introduced and recommended is, I believe, of real advantage, and will prove permanently useful. It is already been copied by others who have seen me operate, and, with a fair field, will find an increasing number of advocates.

I am, Sir, yours, &c.,
John W. Taylor.

59 Bath Street, Birmingham,
10th Jan., 1894.

SURGICAL PITFALLS—DRUNK OR DYING?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As you have amongst your "Notes on Current Topics," in last week's issue of the Medical Press and Circular, in referring, under the above heading, to the case of the late Mrs. Lyons, which has been so recently brought to notice in connection with two Dublin Hospitals, mentioned the name of Dr. Elliott, who is House Surgeon to this Institution, would you, in justice to that gentleman, kindly ask the profession to refrain from forming any judgment or making any comments about him until such time as he will be in a position to defend himself? Dr. Elliott has, I am sorry to say, been confined to bed, not with severe influenza, as you stated, but with a very serious attack of blood-poisoning, contracted in the discharge of his duties. He is still very weak and prostrate, and is thus prevented from in any way refuting the charges made against him or of defending himself.

On Dr. Elliott's recovery, he will, I believe, be able to give a very satisfactory explanation of his conduct on the night on which the alleged ill-treatment of the late Mrs. Lyons took place here.

I am, Sir, yours, &c.,
R. Hill Shaw, M.B.,
House Surgeon *pro tem.*

Mercer's Hospital,
11th January, 1894.

[We have already pleaded for a suspension of judgment on Dr. Elliott, and expressed the opinion that, when his case comes to be heard, it will be established that he has been hastily judged by the Governors of his hospital, and that his action has been misconstrued by the public. We regret to learn of his serious illness.—Ed.]

◆

Obituary.

DR. HARKIN, BELFAST.

The not unexpected death of Dr. Harkin last week deprived Belfast of one of the Fathers of the profession in that city. He received his first qualification, M.R.C.S., from the London College of Surgeons in 1840, his M.D. in Aberdeen in 1859, and was admitted to the Fellowship of the London College in 1859. He served for long as surgeon to the Belfast Dispensary, and afterwards as consulting physician to the Mater Infermorum Hospital. His professional position was recognised by his brethren in the appointment of him to the Presidency of the Ulster Medical Society, and he was the contributor of many papers of interest evidencing much medical acumen in the *Dublin Medical Journal* and *Medical Press and Circular*.

SURGEON-COLONEL HILSON.

The death is announced of Surgeon-Colonel A. H. Hilson, C.I.E., retired list, Indian Medical Service, at Norwood, at the age of 58 years. The gallant officer, who was in possession of a distinguished service reward, entered the Army in 1851, and retired in 1891. He served with distinction in the Indian Mutiny campaign, being present at the actions of Sahunpore, Phoolpore, Belwah, Amorah, Doomerajagunj, and Judepspore (severely wounded), granted medal. He also served in the Bhootan campaign, receiving the medal with clasp.

He became surgeon in 1869, surgeon-major in 1873, brigade-surgeon in 1884, and surgeon-colonel in 1888. He was honorary surgeon to the Agra Volunteer Rifle Corps, Inspector-General of Civil Hospitals, Bengal, and on retiring from active service was awarded a distinguished service reward. He was created a C.I.E. only last year.

DR. MATTHEW J. TURNBULL.

The death is announced at Tweed View, Coldstream, of Dr. Matthew J. Turnbull, who was one of the oldest medical practitioners on the Borders, where he had an extensive practice, and was well known and much respected among a large circle of friends and acquaintances. Dr. Turnbull was originally in partnership with the late Dr. Alexander Brown, surgeon, Coldstream, but since the death of Dr. Brown many years ago he had conducted the practice himself. At one time Dr. Turnbull was one of the medical officers under the Berwick Board of Guardians, acting for the western portion of the district, but this appointment he resigned. He took considerable interest in the public affairs of Coldstream, and at the time of his death was Parochial Board representative on the Middle District Committee of the County Council of Berwickshire.

Medical News.

Hydrophobia in Liverpool.

Hydrophobia has appeared again in Liverpool, and quite recently five persons have been bitten by a St. Bernard dog in the adjacent village of Wavertree. The disease was declared to be present in the dog by Dr. Barron, and the patients have been under the care of Dr. Wearing. The persons bitten were a servant girl, about twenty, and four boys about eight years of age. One of the boys was taken off almost at once to Paris to undergo treatment at the hands of M. Pasteur. The rest followed a couple of days later, a fund having been formed with commendable rapidity for that purpose. A special meeting of the local magistrates was immediately held, and the muzzling order is to be put in force in the district.

Manchester Medical Society.

At the annual meeting on Jan. 10th the following were elected office-bearers for 1894:—President: Dr. John en Maun. Vice-Presidents: Dr. Simeon Holgate Owen, Dr. Thomas Carleton Railton, Dr. William Japp Sinclair, and Dr. William Yates. Treasurer: Dr. Charles Edward Glascott, M.D. Ex-Officio Members of the Committee: Dr. Henry Browne, Dr. Julius Dreschfeld, Dr. Charles Edward Glasscott, Mr. James Hardie, Mr. Frederick Ashton Heath, Dr. Thomas Jones, Dr. Daniel John Leech, Dr. David Little, Mr. Edward Lund, Dr. Arthur Ransome, Dr. David Lloyd Roberts, Dr. Sir William Roberts, Dr. Henry Simpson, Mr. Alfred William Stocks, Mr. Walter Whitehead, and Mr. Thomas Windsor. Elected Members of Committee: Dr. Judson Sykes Bury, Dr. Abraham Matthewson Edge, Dr. Alexander Hill Griffith, Dr. Thomas Harris, Dr. James Mackenzie, Dr. James McNaught, Dr. Siegmund Moritz, Dr. Ernest Septimus Reynolds, Dr. Frederick A. Southam, Dr. John Prince Stallard, Dr. Alfred Harry Young, and Dr. W. Thorburn. Representatives of the Council of the Owens College: Adolphus William Ward, Litt. D., and Edward Donner, B.A. Secretary: Mr. William Coates. Auditors: Dr. Edward Vipont Brown, and Dr. Joseph Collier.

Liverpool Medical Institution.

At the annual meeting held on Thursday, January 11th, the following office-bearers, members of the Council, and Pathological and Microscopical Committee were elected:—President: *Chauncey Puzey. Vice-Presidents: J. Armstrong, P. Davidson, *C. G. Lee, and J. W. Warburton. Hon. Treasurer: *A. Bernard. Hon General Secretary: W. Macfie Campbell. Hon Secretary to Ordinary Meetings: *C. H. Shears Hon. Librarian: T. Bushby. Council: J. M. Chisholm, T. Grimsdale, Richmond Leigh, Percy Marsh, J. Tawse Nisbet, E. J. Phillips, *R. S. Archer, *T. R. Bradshaw, *J. E. Gemmell, *J. M. Hunt, *R. Parker, and *G. S. Stansfield. Pathological and Microscopical Committee: J. H. Abram, F. H. Barendt, A. Barron, *A. W. Campbell, T. B. Grimsdale, G. G. Hamilton, F. C. Larkin, J. R Logan, R. W. Murray, Frank T. Paul, W. T. Thomas, and J. Wiglesworth. Journal Committee: R. S. Archer, W. Mitchell Banks, F. H. Barendt, James Barr, J. E. Burton, William Carter, *J. R. Logan, and *W. Permewan. Auditors: *T. B. Grimsdale and *R. J. Hamilton. Those marked with an asterisk did not hold the same office last year.

Christ's Hospital.

At a recent meeting of the governing body of Christ's Hospital, at which the Duke of Cambridge presided, it was resolved to approach the City Commissioners of Sewers, who are the sanitary authority for the City, with modified plans for the drainage of the hospital, to enable it to be re-occupied by boys until the new school at Horsham is erected. These plans, while admittedly not meeting all the requirements of Dr. Sedgwick Saunders, the Medical Officer of Health, will, it is believed, satisfy every useful purpose without putting the already greatly impoverished resources of the institution to the enormous expense which a complete reconstruction of the drains would necessitate. The Duke of Cambridge will, it is expected, head the deputation to the Court of Sewers. As an evidence that the condemned system of drainage has not been productive of evil results in the past, it is stated that with a constant residential population of 800 boys and staff, 12 deaths have occurred in twenty-four years, and only one of these resulted from an illness originated in the hospital itself.

Odontological Society of Great Britain.

The following office-bearers have been elected for the year 1894:—President: Frederick Canton. Vice-Presidents: London—R H. Woodhouse, Ashley Gibbins, A. W. Barrett; Provincial—F. H. Balkwill, Plymouth; W. E. Harding, Shrewbury; George Henry, Hastings. Treasurer: S. J. Hutchinson. Librarian: W. A. Maggs. Curator: Storer Bennett. Editor of Transactions: Edward Lloyd-Williams. Honorary Secretaries: Cornelius Robbins (Council); J. F. Colyer (Society); Clayton Woodhouse (for Foreign Correspondence). Councillors: London—John Ackery, Arthur Underwood, Harry Rose, C. D. Davis, C. E. Truman, W. R. Humby, W. B. Paterson, Harry Baldwin, John Gartley; Provincial and Foreign—H. C. Quinby, Liverpool; D. W. Amoore, St Leonard's; Wilson Hogue, Bournemouth; G. G. Campion, Manchester; J. McKno Ackland, Exeter; J. H. McCall, Leicester; T. Arkövy, Budapest; A. W. W. Baker, Dublin; F. E. Huxley, Birmingham.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this Journal, price, 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

DR. RENTOUL'S letter on "Unqualified Medical Missionaries" is unavoidably crowded out "at press."

MR. ED. EAST is thanked for his note.

MR. G. C. T.—Thanks, but the material would be more suited to the columns of a lay journal. Try the *Family Doctor* or such media as the *Weekly Echo*. We do not give "hints on health" for the edification of the public.

DR. WATSON.—We are not surprised you have received no "satisfactory reply" from the Medical Council. It is not in the province or power of this body to carry such a suggestion into effect.

DR. W. B. (Assam)—We are obliged to our correspondent for the copy of the *Doctor*, a Hindu medical journal, which he sends us. We have seldom seen a more bare-faced quack publication than this appears to be. It is quite possible to understand, as our correspondent expresses it, that "a roaring trade is done in India by the scamps who bring out publications of this sort."

DR. WILSON.—1. Dr. Dawson Turner's work is the most practical work on medical electricity with which we are acquainted. 2. The work of the late Dr. Hilton Fagge will best answer your purpose.

SIR ANDREW CLARK'S DEFINITION OF GOUT.

"WHAT it [gout] exactly means to other people I do not pretend to know; what it means to me I can tell in a few words. By the gouty state I mean the state brought about in certain constitutions by the retention in the blood and tissues of the body of certain acid and other waste stuffs, and their effects thereon."

SANITARIAN.—The infectivity of tuberculosis is being generally admitted in America now, and several States have already passed a law making it a notifiable disease. Our correspondent will find some reference to this subject in another column.

DR. F. C. M.—The matter is not yet officially notified, but we understand it has been decided on, and that an announcement will be made in the course of a few days.

OFFENSIVE HANDBILLS.

A MOST suggestive and objectionable bill has been lately distributed broadcast, some in the letter-boxes of medical men. It advertises a mixture for females ("the strongest on earth") to be obtained at half a crown a bottle. The name of a "consulting medical botanist" is appended, with an intimation that consultation and advice may be obtained free. There can be no doubt whatever that much more is meant than meets the eye in actual print, and one may reasonably assume that this botanist will fleece any women who are foolish enough to walk into his trap. But surely there must be some way of stopping these disgraceful practices. If not, the sooner this subject is brought forward in Parliament the better. We shall be happy to furnish any Member of Parliament with one of the bills in question.

GENERAL PRACTITIONER (Manchester).—An analysis has been made of the much advertised "cuticura ointment," and it has been found to consist of a base of petroleum jelly, coloured green, perfumed with oil of bergamot, and containing two per cent. of carbolic acid.

DR. S. S.—We had a similar application some time ago, and the matter was referred to the firm in whose name the advertisement appeared.

TALIPES.—Our correspondent, we think, has been treated with scant justice. We should strongly urge him to bring the facts of his case under the notice of the governing body of the institution to which he refers. Usually the claim for travelling expenses is one which is determined by arrangement beforehand.

Meetings of Societies, Lectures, &c.

THURSDAY, JANUARY 18TH.

SOCIETY OF ANÆSTHETISTS (20 Hanover Square).—At 8.30 p.m., Dr. Dudley W. Buxton: A Note on Cardiac Asthenia under Chloroform.

SOCIETY OF ARTS.—At 8.30 p.m., Mr. R. D. Oldham: The Petroleum Fields of India: their Present Condition and their Probable Future. (This meeting will be held at the Imperial Institute, S.W.)

FRIDAY, JANUARY 19TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Medical Section, in the College of Physicians, at 8 o'clock. Papers:—Dr. H. T. Bewley: Cancrum Oris in Typhoid Fever.—Dr. J. W. Moore: An Unusual Case of Facial Palsy.—Dr. H. C. Tweedy: Notes on a Case of General Obstruction of the Portal System.

ROYAL INSTITUTION.—At 9 p.m., Prof. Dewar: Scientific Uses of Liquid Air.

MONDAY, JANUARY 22ND.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES.—At 6 p.m., Dr. Morgan Dockrell: Lecture with Clinical Demonstration on General Points of Diagnosis in Diseases of the Skin.

Vacancies.

Bradford Infirmary.—Dispensary Surgeon (single). Salary £100 per annum, with board and residence. Applications and testimonials to the Secretary on or before Jan. 23rd.

Buckinghamshire General Infirmary, Aylesbury.—Resident Surgeon and Apothecary (single). Salary £80 per annum, increasing by £10 per annum to £100, with board, lodging, washing, coals, and furnished apartments. Applications and testimonials to Mr. George Fell, Solicitor, Aylesbury, before Jan. 29th.

East-end Branch of the Children's Hospital, Sheffield.—House Surgeon. Salary £70 per annum, with board, lodging, and washing. Application and testimonials to the Hon. Secretary on or before Jan. 24th.

Liverpool Infirmary for Children, Myrtle Street.—House Surgeon. Salary £85 per annum, with board and lodging. Applications and testimonials to the Secretary on or before Jan. 22nd.

St. George's Hospital, London.—House Physician. Also an Hon. Assistant Physician. Applications before Feb. 12th.

Appointments

COWPER, J., M.B., C.M.Edin., Medical Officer of Health for the Shanklin Urban Sanitary District of the Isle of Wight Union.

DIXON, F. J., M.B., B.C.Camb., Assistant House Surgeon to the General Hospital, Birmingham.

FARQUHARSON, G. S., M.B. Lond. Univ., M.R.C.S.Eng., L.R.C.P.Lond., Sanitary Surveyor of the Board of Trade for the Port of Southampton (jointly with Dr. Grange).

GODWIN, A. H., L.R.C.P.Lond., M.R.C.S., House Surgeon to the Wallasey Dispensary.

GOVER, L. D., M.R.C.S.Eng., L.R.C.P.Lond., Resident Assistant to the Wolverhampton General Hospital, Wolverhampton.

GRANGE, F., M.D. Lond. Univ., D.P.H. Camb., Sanitary Surveyor of the Board of Trade for the Port of Southampton (jointly with Dr. Farquharson). Also Medical Superintendent of Quarantine under the Privy Council.

HANN, R. G., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer to the Leeds Public Dispensary.

HENRY, R. W., M.B., B.Ch.Dub., Junior House Surgeon to the Birmingham and Midland Eye Hospital.

HILL, C. A., M.B., B.C., B.A.Cantab., M.R.C.S., L.R.C.P.Lond., House Surgeon to St. George's Hospital.

JAMES, W. D., M.R.C.S.Eng., L.S.A., Surgeon for Skin Diseases to the Sheffield General Infirmary.

LOVETT, W. L., L.R.C.P., L.R.C.S.Ed., L.F.P.S.Glas., Medical Officer of Health for the Colne and Marsden Urban Sanitary Districts.

ROOK, A. E., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Eastbourne Union.

THOMPSON, S. R., L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 1 Sanitary District of the St. Olave's Union, Southwark.

VINCENT, H. B., Medical Officer of Health to the Mitford and Launditch Rural Sanitary Authority.

WILEY, A. D., L.R.C.P.Edin., L.R.C.S.Irel., Medical Officer of the Knaresborough Workhouse.

Births.

BARNETT-BENTLIF.—Jan. 11th, at 50 David Place, Jersey, the wife of P. Barnett-Bentlif, M.R.C.S Eng., L.S.A Lond., of a daughter.

STOCKEN.—Jan. 12th, at Winchester House, Ealing, the wife of Leslie Maury Stocken, M.R.C.S., L.R.C.P., of a son.

Marriages.

KERR—HENDERSON.—Jan. 11th, at Booterstown Church, co. Dublin, by the Very Rev. Dean Dickinson, D.D., assisted by the Rev. Prof. Stokes, D.D., T.C.D., Norman Kerr, M.D., F.L.S., London, to Edith Jane, daughter of the late James Henderson, Esq., Belvidere Lodge, Newry, co. Down.

VICARS—HASKETT-SMITH.—Jan. 10th, at St. Mary's Church, Cadogan Square, S.W., Frederic George Vicars, M.R.C.S., L.R.C.P., son of the late Colonel W. H. Vicars, to Eugéne Matilde, daughter of Captain Haskett-Smith, late Cameronian Highlanders.

Deaths.

BOYD.—Jan. 6th, John W. Boyd, M.D., of New Ross (suddenly, of syncope), while in the discharge of his medical duties, aged 78.

BRADY.—Jan. 6th, at his residence, Ross Lawn, Clonmellon, Dr. Patrick Brady.

GRAVELY.—Jan. 6th, at Cowfold, Sussex, Thomas Gravely, M.R.C.S., aged 76.

HUTCHINSON.—Jan. 11th, at 35 Clanricarde Gardens, London, W., Surgeon-General R. F. Hutchinson, M.D., Indian Medical Service, retired, aged 62.

SAUNDERS.—Jan. 7th, at Woodside, St. John's Park, Ryde, Surgeon-General George Saunders, Bengal Staff Corps, retired, aged 74.

STOWERS.—Jan. 13th, at 41 Finsbury Square, London, Adeline, daughter of J. H. Stowers, M.D., aged 4.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CVIII. WEDNESDAY, JANUARY 24, 1894. No. 4.

Original Communications.

INHALATION OF OXYGEN
AS A
MEANS OF MEDICAL TREATMENT.

By G. NEWTON PITT, M.D., &c., &c., &c.

ALTHOUGH I cannot pretend in the present instance to offer any new indications as to the circumstances under which oxygen gas should be administered I have thought it worth while to insist upon the fact that there are various conditions of extreme gravity which may be most successfully combated by its administration. I would also call attention to several cases in which I failed to obtain any marked benefit from its use, and shall hope to elicit the experience of others in this matter. Like many other new remedies its reputed uses are innumerable; and if used indiscriminately we are apt to miss the right opportunities for its use.

The cylinders of compressed oxygen, as prepared by Messrs. Brin, form an extremely convenient method of administering the gas. The oxygen can be diluted with air by means of the bag and tube supplied, and inhaled for a few minutes at a time; but, if care and intelligence be used, and the tap turned on but slightly, the oxygen may be allowed to escape slowly undiluted from the indiarubber tube which may be held close to the patient's mouth. If the inhalation is to be continued for any length of time the tube should lie on the pillow by the patient's face. I am sure that in many cases to obtain benefit, the inhalation of the oxygen should be continued for a long time, and where marked benefit is obtained it may be desirable to administer as much as 10 to 20 feet in the day, or even more.* The 10 foot cylinder is sufficient for temporary use, but otherwise the 20-40 foot size is preferable. The amount of oxygen remaining in a cylinder is estimated by the weight—five gallons weighing one ounce and costing 5d., and a cubic foot of gas may be reckoned as six gallons.

RESPIRATORY CASES.

Mrs. B., æt. 35, had been confined six weeks previously. She had returned from Brighton five days ago, and while tired on the journey home was wetted through in the rain. Next day she had a rigor and was seen by Mr. Capes. Pneumonia developed at the right base with a temp. 103°-104°. On the fifth day the temperature fell rapidly, and was below normal at night. The patient became very collapsed and exhausted, and when I saw her the pulse, which was feeble and running, reached 140, and there was considerable dyspnœa. The patient was very emaciated and feeble, and her countenance livid and bathed in sweat. At the right base the impairment of resonance was very marked up to the 8th rib, the râles were consonating, breathing slightly bronchial in places. A patch of bronchial breathing had recently developed over the 8th space on the right side as well, with some pectoriloquy. The breathing was very rapid and shallow, and the patient in such a lethargic and barely conscious condition that it appeared as if a fatal termination was almost inevitable. Brandy ℥viij., and champagne nearly Oj., were given during the next 24 hours, and a mixture of nux vomica, ammonia, and tolu were ordered every three hours.

As soon as a cylinder of oxygen could be procured the gas was inhaled at intervals. The disappearance of the lividity and the extraordinary improvement in her appearance was most marked. The gas was then inhaled continuously with the tube resting close to her mouth, and by the morning her condition was quite changed. The lividity was much less, and she was more conscious. From this time she continued to improve, and ultimately recovered. About 20 feet of oxygen in all was consumed.

The beneficial effect of the inhalation of the oxygen was so obvious and marked at the time that there can be little doubt it was the means of saving the patient's life.

Man, æt. 25, a drunkard, who had pneumonia at the left base, which spread up rapidly, giving the following physical signs: Dulness up to 8th rib, bronchial breathing with crepitation and widely spread râles over both chests. He took his food well, but had severe diarrhœa, and slept badly. On the 5th day the pulse was 120, and his strength was failing. In spite of stimulating treatment he died. Oxygen inhalations more or less continuously for some hours did not benefit him. The whole chest was filled with râles on the last day.

A man, æt. 65, a drunken bargee, came in on the fourth day of pneumonia at right apex. He was mortally ill, and oxygen did not avert his death within twelve hours.

A sickly child, æt. 3, with broncho-pneumonia, had been ailing for some time. Numerous râles over the chest with two patches of bronchial breathing; temp. 102°, pulse 120, respiration very rapid. The child became very drowsy, was bathed in sweat, and extremely ill on the 3rd day. With stimulation and oxygen inhalations it was kept going, and after two days it improved and recovered. The effect of oxygen at times was to afford great relief, but not always.

Miss C., æt. 25, with early phthisis of a fairly quiescent type at the right apex. After exposure she developed an acute attack of dyspnœa, with temperature 105·6°. Upon examination there was found at the right apex, as before, deficient resonance with a few crackling râles and diminished voice sounds, but at the root of the right lung there were some fresh râles, with deficiency of breath sounds over the base. The lividity, pain, and dyspnœa continued in spite of all treatment, and were very severe. Oxygen inhalations were found, however, to give more relief than anything, and at first were employed for ten minutes at a time, but after a short time continuously. The relief afforded by it was very great, and was most marked when the temperature was high. The pulse was over 150, and for many days the patient's condition was most critical. The signs pointed to an acute tuberculosis, but when seen nine days later, it was clear that there was a pyopneumothorax, the contents being sero-pus with very little gas. The chest was aspirated, and as soon as possible drained, to the great relief of all the symptoms. Previous to this drainage, about 10 feet of gas were inhaled each day with marked relief to the symptoms, with diminution of lividity, and a great improvement in the pulse. Gradually the condition improved so much that the patient was able to get about a little, but the sinus never closed up. As the phthisis progressed the inhalations were frequently tried for the relief of the dyspnœa and of the lividity, but they were then of little benefit.

In the case of a young girl, æt. 21, with steadily progressive phthisis and emaciation with physicial signs of consolidation followed by cavitation at the right apex, there were attacks of dyspnœa which were very distressing. These came on after midday or at night. The temperature varied from 102° to 104°, and gradually moist, and ultimately consonating râles developed over the left chest behind.

Inhalations of oxygen certainly relieved these attacks and quieted the pulse, the patient generally asking for the oxygen.

In two other cases of advanced phthisis with dyspnœa, rapid pulse and emaciation, oxygen was frequently administered, but without relief. The dyspnœa was more constant in these cases.

Uræmia.

I administered oxygen frequently to a patient, æt. 55, with chronic Bright's disease, the kidney probably being a contracted and granular one. She had a albuminuric retinitis, and at times passed into a dull state of semi-stupor with great drowsiness, occasionally there were slight muscular twitchings, but never any convulsion. Her bowels were kept freely open, and she was on a farinaceous diet. It has been stated that such conditions of chronic uræmia are much benefited by the frequent inhalation of oxygen, in this case no decided effect was produced. On one or two occasions only did she appear to be in any way improved.

Two cases of uræmic coma, in which I administered oxygen, were not benefited by it; my personal experience of it in such cases is not in its favour.

Coma.

Dr. C. Cripps has urged the great value of its use in other forms of coma, particularly that due to toxic agents, such as opium. It undoubtedly, in cases of apoplexy, relieves the extreme lividity due to the engorgement of the lungs, as in one case of mine, where, however, it in no way retarded the fatal ending.

Where coma was profound and it appeared likely that the pulmonary aeration would be very defective, it might be worth while to administer the gas continuously from the onset.

Convalescence.

In cases of convalescence from severe illness with a very feeble cardiac condition, in some cases of neurotic patients with small pulse and a liability to syncope, and in cases of mitral stenosis with considerable pulmonary engorgement and a barely perceptible pulse I am sure that oxygen inhalations will be found a considerable adjuvant to other treatment. From seeing an account of the great benefit received by a convalescent patient from oxygen, I used it in a case of a very feeble patient who was very liable to attacks of syncope and palpitation after an illness, and we found that the patient brightened up and the attacks of cardiac failure could be staved off, while it seemed to act as a general fillip to her appetite and to all her functions.

Anæmia.

In cases of anæmia, and especially of chlorosis, Hayem has shown that oxygen inhalations improve the appetite, digestion, and general condition, increasing the number of red-cells, but not the amount of hæmoglobin; the patient is better able to tolerate iron and so recover sooner. The effects of oxygen are only temporary, and it is only useful as an adjuvant; the patients fall back when it is discontinued.

Albrecht found that 50 anæmic, but convalescent children lost their anæmia, while their appetite and digestion improved when oxygen inhalations were administered regularly. The question of expense and trouble, however, will prevent its frequent use, but in exceptional cases its value must be borne in mind.

Cases are recorded of pernicious anæmia and leucocythæmia which have been markedly benefited by oxygen, but of this I have no personal experience. Dr. Taylor will, perhaps, kindly give us his views, as I believe he had a case in which the results were very obvious, but most are agreed that the benefit is seldom permanent.

Anæsthesia.

Another valuable use for oxygen is in cases of troubled respiration when it is necessary to administer an anæsthetic. Here it has in several instances been of the greatest value, and has greately diminished the risk of operating upon large empyemata where it may be necessary to turn the patient on his side.

In laryngeal diphtheria with obstruction and with collapsed lung or membrane passing down the bronchi, I have in several cases administered oxygen. In no case with any marked benefit, and in some without any appreciable effect. In two the lividity was slightly diminished, but the fatal termination was not appreciably postponed.

The absorption of the full amount of oxygen that the blood in the capillaries can take from the alveoli is so rapid and complete that it is not increased by substituting oxygen for air. This would appear to afford a partial explanation why the inhalation of oxygen has failed to relieve the respiration in cases of laryngeal obstruction, but of course the over-distended right side of the heart, induced by the inability to expand, is a most potent cause of dyspnœa which remains unaffected.

Still, when the air remains unrenewed for long in the alveoli the volume of oxygen must ultimately fall below 12 per cent., which is that of venous blood; this stage would be postponed it would appear if oxygen had been inhaled and so the patient would benefit. It must be allowed that there is still uncertainty why the oxygen often fails to relieve lividity in cases of respiration obstruction, and in what way such cases differ from others in which relief is so marked.

To sum up. The inhalation of oxygen is of marvellous value in some cases of severe pneumonia, especially when there is much lividity and cardiac failure and at the crisis.

It fails in other cases, and I should be inclined to suggest that where the condition is one of mainly cardiac failure and collapse more benefit is obtained than in cases where the serious condition is especially due to a widespread œdema or bronchitis; but on this difference between the two classes of cases I should be glad to learn the experience of others.

Some cases of severe bronchitis and asthma have, however, been benefited by oxygen. In one case of acute upon chronic bronchitis in an elderly lady I saw some, though not very marked, relief of the dyspnœa.

2. In cases of empyema, pneumothorax, and pleuritic effusion great relief can be afforded to the dyspnœa and cardiac failure until operative measures are undertaken.

3. Cases of feeble patients with phthisis may be relieved, but more often there is no marked change.

4. Cases of weakly convalescents and feeble cardiac cases will often derive great benefit, and inhalations may be given periodically for weeks; but oxygen will not restore to health, it must simply be used as an adjuvant.

5. Cases of chlorosis, pernicious anæmia, and leucocythæmia receive great temporary benefit, but the oxygen must be supplemented by other drugs.

6. Conditions of asphyxia and lividity from respiratory engorgement due to cerebral failure and also coma from various cases may be relieved.

7. Its value in uræmia, though insisted upon by French writers, is still problematical.

8. It may also be of value in diminishing the risks of anæsthesia.

◆

NOTES ON A CASE OF
VENTRAL HERNIA FOLLOWING LAPAROTOMY.

By JOHN J. M'ARDLE, F.R.C.S.I.,
Surgeon to St. Vincent's Hospital.

B. M'G., æt. 27, was sent to me from Louth, labelled urgent. I must say I never saw any urgency about the case, and the details given by the patient as to the origin of her trouble only proved how little we laparotomists are appreciated by the ordinary public. The man who avulses a toe-nail, or passes a Eustachian probe, is a genius in the estimation of the ordinary run of observers, while if we safely guide a case through the dangerous stages of a prolonged laparotomy, and she afterwards gets a curable though enormous hernia, all the credit of a brilliant performance vanishes, and she calmly tells us, or more likely some one else, "The operation ruined me." We know the value to set on such statements. This was such a case, and I approached it with some concern, especially as Drs. Horne, Smith, and myself concluded that a hydrops peritonei was present, and that the patient was not over-vigorous.

I operated on this case on Nov. 14, 1893, assisted by Dr. Smith. Reaching the neck of the sac at one point, I attempted to follow it round, but I failed to do this owing to a sacculation, and was, therefore, obliged to dissect out each sac separately. After examining the interior of the sac I passed a purse-string suture round its neck, and tied it firmly; section of the sac half an inch above this suture was rapidly carried out. While this was being done Dr. Smith held sponges firmly against the cavities from which I had removed the sacculi. I now passed six silk sutures through the firm and freshened aponeurotic ring, drawing the edges well over the fulness produced by the purse-string suture of the peritoneum. These were cut short, and I applied myself to checking bleeding from the subcutaneous tissues. Owing to their great vascularity I was obliged to pass a double thread from the extreme limit of the dissection on one side, and bring it along under the tissues of the floor of the incision and out on the opposite side, so that when I tied down a pledget of gauze on each side the entire centre of the cavity, from which I removed the hernial sac, was obliterated. This deep supporting suture and the skin sutures, applied as I shall hereafter describe, effectually checked the hæmorrhage and completed the operation. A very free discharge of clear serum, amounting to more than half a gallon, took place from the peritoneum when the sac was opened.

There is a disposition to complete operations on the abdomen by passing a row of deep sutures embracing the entire thickness of the abdominal wall, and intermediate superficial sutures usually securing skin only.

(*a*) How often do we in passing the deep sutures revert to the fact, that there is a great tendency to retraction on the part of the essential constituents of a sound abdominal wall. My motion is that many cases depend for complete restoration of the abdominal wall on contraction of a very extensive cicatricial deposit between the widely separated lips of the aponeurotic opening. The failure of one or two sutures to engage a considerable mass of the mid-stratum of the abdominal wall would account for many of the protrusions which follow laparotomy.

(*b*) In the conduct of abdominal sections there is a tendency to use ordinary catch forceps for the support of the peritoneum. I have noticed that many of these bite very hard, and seriously reduce the vitality of tissues subjected to such vigorous pressure. The parts supported by the forceps are drawn at times well up between the layers of the abdominal wall and fixed there by the sutures. During repair these points become the seat of vigorous tissue change, with the object of remedying the ill-effects of over-pressure; if lymph accumulates it must separate the tissues, and as the peritoneum unites rapidly behind the effusion the fluid presses forward and separates those layers which are slow of healing, the aponeurosis being last of all to firmly unite, the tendency is to thus cause a faulty union. To avoid this I have used sharp-pointed forceps so bent that they lie flat on the abdomen, and do not interfere with the further steps of the operation.

(*c*) Occasionally, too, unless all the layers of the abdomen are drawn together, a hæmorrhage occurs during reaction, the skin-wound is closed accurately, exudation has glued the peritoneal surfaces together, and the blood remains between the layers of muscle or aponeurosis, as the case may be, preventing early union, and any vigorous effort causes rupture.

(*d*) Again, low vitality permits lymph exudation to break down, or possibly direct infection sets up a circumscribed suppuration. This prevents the edges of the mid-stratum uniting, and hernia follows.

There are thus many causes of want of union of this essential layer of the abdomen, and I would place them in order of importance—

1. Failure to engage the different layers of this stratum sufficiently in the sutures.
2. Interposition of contused peritoneum.
3. Hæmatoma not becoming soundly organised.
4. Suppuration from inherent or extrinsic causes.

The remedy for this is to suture the abdomen in all laparotomies as we do for hernias, to obliterate all cavities in which blood or serum could collect, and to avoid contusing the peritoneum by using catch forceps such as I suggest, with sharp points.

The steps of the operation, as I believe it should be conducted, are—Incision of skin on one side; isolation of the neck of the sac along this side, then undermining not only the skin, but all the tissues on the other side of the neck, making it possible to cut cleanly through everything down to the neck of the sac with a strong scissors with long handles. This done, and being satisfied by opening the sac that no omentum or bowel remains in it, a Hagedorn's needle is carried round in the sub-peritoneal tissues, like a purse-string. This being drawn and tied, numerous sutures carried with the same needle through the aponeurosis, close the wound over the mouth of the purse after cutting away the sac a quarter of an inch or so above that ligature. Skin sutures passing deeply, and taking up the floor of the wound, are now applied and knotted, and the operation thus completed.

I may add that I consider subcutaneous wire sutures to be ineffectual and dangerous.

◆

COLECTOMY
FOR ADHESION OF CÆCUM TO AN OLD OVARIAN PEDICLE AND TUBERCULAR APPENDIX.

By A. J. SMITH, M.B., R.U.I.,
Ex-Assistant-Master Rotunda Hospital, Dublin.

A young married woman, name Mrs. G., æt. 24, was sent up from Westport to my gynæcological wards in St. Vincent's Hospital towards the end of September, 1892. She had been then married four years, and had three children, each at full term and healthy. About a month after the first confinement she complained of pain in the right inguinal region, referred to a point midway between the umbilicus and the anterior superior spine of the ilium.

The ovary, when removed, was found to be a fine specimen of hydrops folliculorum. It is preserved in the Museum of the Royal University. [Engraving of specimen was shown.] Pain continued after operation, which necessitated a second exploratory incision six months after, revealing an enlarged left ovary, with cystic degeneration and extensive adhesions between cæcum on old right pedicle.

Adhesion was so intimate that resection of intestine was necessary to separate it, but Mr. M'Ardle agreed with me that such an operation in the patient's present condition would militate against her recovery, so we reluctantly closed abdomen after removing left ovary and tube.

After the second operation in May it was hoped that the intolerable pain would be benefited. Such was not the case. At first there was temporary relief, but soon the old dragging pain returned with renewed intensity, specially at night, and the patient was confined to her bed, a burden to herself and her family. Nothing was left to be done except to separate the adhesion.

I again admitted her to St. Vincent's Hospital in the second week of November last and made a careful bimanual examination. The uterus was still normal in position; the right pedicle, with its adherent intestine, could be easily felt as a thickened indefinite mass; it was distinctly tender. Nothing calling for note was felt on examining the left pedicle. I inverted the patient on Tredenlenberg's table and opened the abdomen a little to the right of the mesial line. There was a slight omental adhesion along the track of the old incision. Before I could put my finger into the pelvic cavity I had to draw aside the omentum and the small intestines—they had become anchored to the pelvic organs by fine adhesions. There was some difficulty in getting the adherent pedicle well into view, but eventually it was brought well up to the abdominal incision. A narrow sponge held by an American forceps was placed under the arch formed by the adhesion; the intestines were protected by sponges wrung out of a warm saline solution. The pedicle and cæcum were now held tense by Mr. M'Ardle whilst I separated the adhesion. To our surprise pus welled up; this was mopped up with moist corrosive wool, and the separating process continued, revealing an extensive ulcerating cavity, formed by the end of the old pedicle, a portion of the wall of the cæcum, and the vermiform appendix. I carefully disinfected the ulcerating surfaces with corrosive sublimate solution 1 in 1,000, and proceeded to deal with each affected portion in turn. The pedicle was short, quite close to the uterus; it was swollen to the size of the last phalanx of the thumb. Many large veins could be seen around its border; they looked like hæmorrhoids, and concealed the ulcerating surface like a monk's cowl. On unfolding the cowl the old silk ligature was found lying quite loose, and apparently unchanged. [Specimen here shown.] The substance of the stump was very rotten, and gave way easily on the least tension. I transfixed it with a stout silk ligature and tied cautiously, and then cut away the ulcerating surface. I ligatured the vessels separately.

The vermiform appendix was next treated. Its behaviour was decidedly interesting—it was quite turgescent like a semi-erect penis, and beat regularly, the rhythm of the beat synchronised with the pulse. Its crown or apex was eaten away by an ulcer of tubercular character, and its stem greatly thickened. The appendix was now held upright whilst I made two oblique incisions through its peritoneal covering, then peeled the peritoneal layer back, as one does the prepuce in circumcision, and amputated the central portion. The tops of the two flaps were next inverted and brought together by two No. 4 silk sutures (as diagram). The ulcer on the cæcum was the size of a two-shilling piece, with undermined edges; it was tubercular; its base was slit across to find its extent, and it was found to penetrate as far as the submucous tissue. The intestine was held up by Mr. M'Ardle, and the entire ulcerating surface was snipped off with scissors, leaving healthy tissue on all sides. The submucous tissue was brought together by a purse-string suture (see diagram); then the muscular layers by interrupted (No. 4) silk sutures, taking in the edge of the peritoneum (see diagram); and, finally, the peritoneum by Lembert's sutures (see diagram); the pelvis was dried and a drainage-tube inserted. The operation, now complete, was performed under sixty minutes.

On recovering from the ether very excessive and persistent vomiting set in, which was so distressing and accompanied by such great abdominal pain that, contrary to my usual practice in abdominal sections, I was compelled to administer ¼ gr. of morphia hypodermically, fearing that the exertion and strain of vomiting might do some damage. About three hours after the operation it was noticed that the temperature was 97° F., pulse 110, and the dressing was soaked with blood. I dressed the case and aspirated out of the drainage-tube about a tablespoonful of very dark blood. I hoped that this dark-coloured discharge pointed to a cessation of the hæmorrhage, and I gave orders for the pulse and temperature to be taken every half hour, and the dressing to be watched. The patient was under morphia, but on the effects passing off, vomiting again returned about 9 o'clock p.m. I happened to be present, and noticed the patient got very pale; pulse 120; temperature subnormal. She complained of severe pain in the abdomen and the sacral region. Her appearance showed much distress. I considered the pedicle ligature must have slipped, so telephoned to Mr. M'Ardle, who kindly came at once. Both of us took extraordinary care to render our hands thoroughly aseptic. The patient was too weak to be removed from the bed, so, with the aid of candles held by nurses, I reopened the abdomen. Blood welled up, just like the hæmorrhage in a ruptured tubal pregnancy. Two fingers slipped down to right side of uterus engaged all the tissues, and effectually checked the hæmorrhage, while the large blood-clots were rapidly removed. We then saw that the silk ligature had cut through the rotten pedicle and was hanging on to a shred. How were we to stop the hæmorrhage—there was no pedicle left? We accomplished it by transfixing part of the uterine wall with a stout silk ligature, tying in two bundles; this controlled the hæmorrhage. For extra safety separate ligatures were put on the vessels. I took the opportunity of examining the intestinal suture, and found the suture track well glazed. I then flushed the abdomen with a warm saline solution and left in a drainage-tube; the excess of saline fluid was not aspirated—it was left to be absorbed by the peritoneum, the anæmia of the patient was so great.

Her recovery was uneventful, and was remarkably afebrile. The pains are all gone. All the incision stitches were removed on the eighth day, except the suture in the drainage tube track, which was taken out on the tenth day; union perfect.

What was the cause of the pain—I believe now that there was originally a tubercular deposit in the appendix; a low form of inflammation was set up, and it became adherent to the cæcum, infecting it; its subsequent adhesion to the pedicle stump was a mere accident. Critically, I believe this to be the case, and the severe pain suffered by the patient was the same in position, intensity, and character as that for which she was originally operated on; and that the coincidence of an enlarged and painful ovary, accompanied by severe menstrual floodings, caused the condition of the appendix to be overlooked.

I beg to call attention to the fact that this case illustrates—

1. The value of drainage.
2. The rapidity of glazing after suture of the intestine.
3. The rapidity of suture by the purse-string and Lembert's method.
4. How, even after very copious hæmorrhage, death may be arrested by prompt treatment.

And 5. The necessity for careful examination of the vermiform appendix in cases of persistent right side pain.

◆

A MECHANICAL TREATMENT OF PHTHISIS.

By NOBLE SMITH, F.R.C.S.Edin.,
Surgeon to the All Saints' Children's Hospital, and Surgeon to Out-patients, City Orthopædic Hospital.

I AM about to describe, as an entirely new remedy for tubercular disease of the lungs, a method of mechanically expanding the thorax and of permanently enlarging the aerial capacity of the lungs.

The *modus operandi* of this treatment is based upon facts long established and accepted by physicians, and although I am for the first time publishing this method, I have been for many years watching the effects upon a variety of patients suffering from various troubles of the respiratory apparatus.

I will, in the first place, assume that the following statements are accepted facts:—

(1) That the deposit of tubercle is more prone to occur at the apices of the lungs than at other parts.

(2) That in a large majority of cases of phthisis, disease commences in these situations.

(3) That the reason of tubercle deposit occurring firstly in the apices, is the less liability of those parts of the lungs to be fully aerated.

(4) That this lessened liability to aeration depends upon (*a*) the mechanism of respiration; (*b*) upon the general want of physical stamina of the patients, leading to a lessened effort of respiration, and a lessened liability to hold the body erect.

(5) That all measures which tend to increase the vital capacity of the lungs—such as outdoor occupations and exercises which develop the thorax—also tend to lessen the progress of tubercular disease, and even materially to help to cure that disease when it is dealt with in the early stages.

(6) That whatever other remedies may be desirable, the increased aeration of the lungs with pure air is of immense value in the treatment of consumption. Physicians have aimed at killing the tubercle bacilli, and they have failed. It remains for them, however, to render the soil unfit for the cultivation of these bacilli, or, in other words, to so increase the patient's vitality that tubercle cannot thrive upon them. To increase the vitality to the greatest extent we have to employ various remedies—climatic, dietetic, medicinal, and hygienic—and we all know how much depends upon the careful application of these measures.

It is difficult to imagine that any very notable improvement in the above remedies, unless it be under the head of "medicinal," can be effected. As regards the greater expansion and more thorough aeration of the lung cavity, very little has yet been done, and I think that the plan of treatment I am about to describe is incomparably superior to all other methods that have ever been advocated for the attainment of the same object. In fact it is the only method by which a sustained condition of greater expansion can be effected while the patient is at the same time getting about and carrying out all the other details of treatment which come under the heads already quoted.

Dr. Sylvester, who, as the author of "The Physiological Method of Inducing Artificial Respiration," has a world-wide reputation, recognised the great importance of this object of treatment. He wrote a pamphlet entitled "The Physiological Method of Treating Consumption," in which he urged most strenuously the value of increasing the vital capacity. He referred to the inability of phthisical patients to use sufficient exertion to fully expand their lungs. He described how he had inquired as to the weight of the upper extremities, and that according to experiments carried out for him by the late Mr. John Wood, the average weight of the arms in males was 7 lbs. 7 ozs., and in females 5 lbs. 10 ozs., and that when the individual was deficient in strength the influence of these weights caused a depression on the upper ribs, and materially impeded the aeration of the apices of the lungs. He experimented with the spirometer, and found in a certain number of individuals that with the arms hanging down, the number of cubic inches of inspiration being from 150 to 180, this volume was directly increased to 190 when the arms were supported upwards. Even when the patient retains an upright posture the arms tend to slide forwards and depress the thorax, and it will be found that the scapulæ are then drawn forwards from the central line of the spinal column, as shown in diagram A, which represents the shoulders looked at from above downwards, whereas the appearance should be as in diagram B.

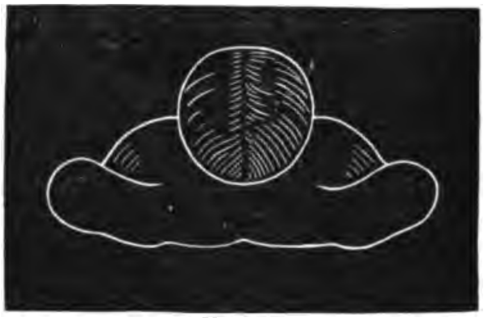

FIG. A.

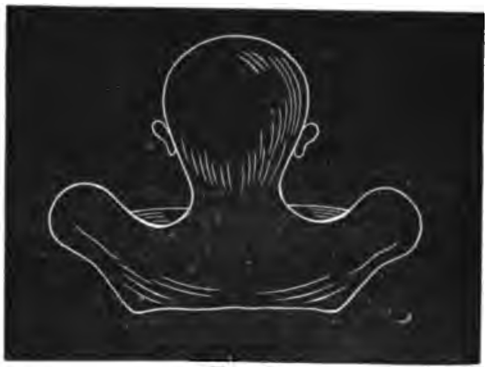

FIG. B.

These two figures are copies of sketches which I made from a patient (A) before and (B) after treatment had been carried out for a few weeks. This is only one case out of a large number. There is frequently also a great inclination to stoop, and the stooping position greatly increases the depressing effects upon the thorax. It is upon patients where there has been a stoop that my experiments have been chiefly made, and I have already described the pernicious effects of persistent stoop upon the respiration. Phthisical patients have a great tendency to stoop. The stooping attitude prevents the proper action of the ribs, and so lessens thoracic respiration, and impedes the breathing to a very serious extent. The abdominal muscles are also relaxed, and the power of acting upon the abdominal visceera in the processes of expulsion are interfered with. The chest is invariably flattened, and the action of all the viscera interfered with.

The researches of the late Dr. Hutchinson upon the movements of the thorax show conclusively how important a matter is the maintenance of a natural "vital" capacity. This is, of course, a large subject, and one which I will not trouble you by dilating upon.

Dr. Sylvester, in devising a plan of treatment to deal with this difficulty in cases of consumption, advocated a chair with arms sufficiently high for resting a patient's upper extremities, and with a frame-work above with pulleys for the patient to exercise the arms held above the head. He also suggested a plan by which the patient could stand erect and use two slender poles about six feet long, one in each hand, placed perpendicularly, one on each side of him, the lower parts of the poles resting on the ground a little in advance of the heels, and by raising his hands, clasping the pole as high as he could conveniently reach, so as to allow the weight of the upper extremities to be borne by the poles instead of by the patient. Then, expanding the chest, he was to draw a deep inspiration for about two seconds. He remarked that tubercular deposits in the air cells were practically outside the body, and that by the free entry of the air to the parts affected the tubercular matter might be eliminated, and the site undergo a sort of repair, the cavities gradually contracting, and ultimately becoming obliterated.

I am now, however, treading upon ground which is far better known to my readers than myself, and regarding which I cannot pretend to speak with their authority, but I think they will admit that whatever may be the exact process of benefits derived from complete aeration, there can be no doubt that such benefits are very great. The results obtained by Dr. Silvester were of a very encouraging kind. As far as this treatment went it seems to have been beneficial, but although Dr. Silvester's plan effected in the treatment of phthisical patients, such treatment continued necessarily only for very short periods at a time. If a patient will rest in a chair with the lumbar part of the back supported, and the shoulders thrown back, and the elbows resting upon very high arms, the chest may undoubtedly be placed in a good position, but for how long a time is this to be maintained?

Whenever the patient moves from that one position, or stands up, or does anything else but sit in that one constrained attitude, the chest falls down to its old position, and not only is the effect removed for the time, but there is very little probability of a greater development of the thoracic capacity. Then, again, as regards exercises, undoubtedly Dr. Silvester's method is a good one, and tends very much to develop the chest; but let us consider the amount of time which a patient can devote to this exercise. Even if the health be good, and the patient comparatively robust, he cannot be always sitting in a chair exercising, or walking about with poles to support him, let alone the peculiarity and irksomeness of the occupation, and therefore one cannot expect to get more than very limited results.

There is another point which has to be considered: the physical strength of the patient, which in cases of phthisis, or threatened phthisis, is considerably depressed; so much so, that they are generally unfitted to go through sufficient physical exertion to correct the depressed condition of the chest, and they are very often harmed by any attempt to use such exertion. Gentle exercises—which in their case will be found beneficial—will be very much exceeded by attempts to forcibly increase the chest capacity.

My plan of treatment consists in drawing the shoulders backwards by soft shoulder straps to a pad placed centrally between the scapulæ, and permanently held so. There are many so-called *braces* largely advertised in the present day for effecting this purpose, and if my plan consisted in nothing more, it would be open to the grave objections which I raise against these patent braces. They pull the shoulders back, and give a false appearance of improvement, but they do nothing to relieve the chest from the weight of the arms themselves. Consequently, you will find upon a close examination, that the chest is little—if at all—increased in capacity, while there is so much constraint due to the enforced position of the shoulders, and the spine is almost sure to curve in one or other direction. The braces, moreover, tend to pull the shoulders downwards, and so increase the weight which has to be sustained by the trunk. My plan consists in keeping the central pad to the level of the shoulders, and so producing a somewhat upward support, by carrying a light steel rod down the back to the level of the seat, there to be maintained by a pelvic belt.

With this alone we find that there is a tendency in sitting for the spine to project backwards, and in standing, for the abdomen to sink forwards, causing a condition of lordosis. To obviate these postures a pad is placed in the centre of the back to prevent the backward projection in sitting, and a belt is placed in front of the abdomen to limit its projection while the patient is standing.

My practical experience of the results of this treatment is of the most satisfactory kind. Although I have not dealt with patients simply for the treatment of phthisis, the cases which have come before me clearly indicate the benefits which such patients would derive from the method.

On May 11th, 1886, a young lady, æt. 16, was sent to me by Dr. Charles Myers, of Louth. She had been very delicate from the age of 4, after measles and dysentery. The weakness increased during the summer of 1885, exaggerated again during the first months of 1886. She had drooped her head forwards during the last three years, the spine curved backward, the chest was flattened, so that it formed a vertical line with the abdomen. Her appearance was that of a phthisical person; she was ashy pale with a hectic blush, and as several members of her family had died of tubercle it was naturally feared that this patient was similarly affected. She had suffered from almost constant cold and cough during the last two and a-half years. Upon percussion I found some dulness over the apex of her left lung. There was pain in the region of the eighth, ninth and tenth dorsal vertebræ, and the seventh projected slightly. I treated this patient in the manner described above, allowing her to get about as much as she liked.

By gradual adjustment at intervals I brought her into an upright position, care being taken never to cause discomfort to the patient. Great relief to all the symptoms was experienced almost from the commencement of treatment.

In a week the dulness at the left apex was gone, showing that the air now entered the lung fully. The improvement in the whole health was very rapid; the cough ceased, pain in the back went away, the appetite improved, and on July 27th—less than six weeks from the commencement of treatment—I was able to note, "No pain, looks better, stouter, and brighter," in fact, the change in her appearance and health was very remarkable. She has continued to improve, has become stout and robust, with good colour. I have seen her within the last few months.

Another case was that of Miss M. F., æt. 9, sent to me by Mr. T. E. Parsons, of Wimbledon, September, 1885. She had been subject to a spasmodic cough for several years, and could not sit up straight. She had been seen by many eminent physicians, but the exact cause of the cough was obscure. The chest, however, was much contracted, and phthisis was feared. From the day on which the apparatus was applied this child began to get better, and in a few weeks the cough left her. I saw this patient about two months ago (June, 1893); she had grown to be a fine girl, perfectly robust; her health is perfect, and she is an excellent figure.

I could add dozens of similar cases, but I have selected these two because they are some of the earlier cases of which I have full records, and because I have recently seen these patients and can report on their present condition.

In advocating this new plan of treatment, or perhaps I ought to say *item* in the treatment of phthisis, I wish it to be most thoroughly understood that I am not advocating it in the place of other measures. We all know the value of a combination of every remedy to counteract the ravages of tubercular disease, and to do the best for any patient undoubtedly involves a large amount of trouble and attention. A high and dry situation, a comparatively mild atmosphere, pure air, carefully selected foods, probably also massage, and various medical remedies, are all necessary, but I would add that until we have mechanically increased the vital capacity of the lungs, and have taken measures to keep the patients in an upright position, with their arms supported without great muscular effort on their part, we have not given those patients the best chance of improving their health or recovering from one of the most prevalent diseases with which this country is afflicted.

The question may still occur to some of my readers—Why not develop the chest by exercises? I have already answered that question, but I may reiterate that a great many of the patients are far too feeble to be able to carry out prolonged or systematic exercises. If they are strong enough, by all means let them be drilled and taught to take prolonged inspirations, but the effects thus produced will be infinitesimal in comparison with the result of mechanical development. The effect of the latter is *immediate*, is *continuous*, and is without the effort of the patient. The former process is *slow*, is *interrupted*, and is only produced at considerable and generally harmful expenditure of muscular exertion.

The apparatus which is necessary to carry out this treatment is comparatively light; is felt as a great support and help by the patient; it does not interfere in the slightest with development; it allows perfect freedom of use to the muscles, and upon the whole is fully appreciated by the patient on account of the personal comfort derived from using it, and the immediate and rapid benefits to the general health.

◆

Selected Prescriptions and Therapeutic Notes.

29—For Insomna in the Acute Infective Maladies of Children:—

℞ Chloralamide, gr. xv;
Liq. ammon. acetatis. ʒijss;
Syp. simplicis, ℥ss;
Aq. distill ad ℥viij.

M. Sig. One teaspoonful every four hours (for a child of three years.)—M. MARCUS.

30.—Carbolic Acid in Pruritus.—The following preparation is highly spoken of:—

℞ Acid carbolic, ʒjss;
Liq. potassæ, ℥j;
Ol. lini, ℥j;
Ol. bergamot, ʒiij.

M. Shake well before using.—DR. BRONSON.

31.—For Acute Articular Rheumatism:—

℞ Acid, salicylic, ʒjss;
Alcohol. absolut., f℥j;
Olei ricini, f℥ij.

M. Sig. Apply topically morning and evening by means of saturated compresses, covered by an impermeable dressing and held in its place by a flannel bandage.—RUEL, *Rev. Méd. de la Suisse Rom.*, 1893.

32.—A Simple Remedy for Coryza:—

In the *Revue Medicale*, the following is given as an excellent remedy for coryza. A ripe lemon is taken and some of its juice squeezed into the palm of the hand. The juice is then forcibly inhaled up the nostrils. Two or three such inhalations will suffice, it is said, to cure an ordinary cold.

33.—Nitro-Glycerine in Sciatica:—

Dr. Lawrence (*Revista de Ciencias Medicas de Barcelona*) reports the case of a carpenter, æt. 52, who suffered for several weeks with sciatica. In order to alleviate the pain he had become a morphine user and could not abandon the habit. After trying a multitude of drugs he gave him a 1:100 solution of nitro-glycerine, one drop three times a day, gradually increasing the dose to five drops. Relief was almost immediate, and in ten days he could resume his work, completely cured.

34.—Epistaxis.—Plethoric cases are relieved by:—

℞ Tinct. aconit., gtt. viij;
Liq. ammon. acetat., ℥i.

M. Sig. Teaspoonful every half-hour.

In anæmic cases may be employed:—

℞ Strychniæ sulphat, gr. $^1/_3$;
Tr. ferri chlor., ʒij;
Vini ergotæ, ℥ss;
Syr. simplices, ℥iss;
Aq. destill. q. s. ad ℥vj.

M. Sig. Teaspoonful three times a day.
Medical Bulletin.

35.—Ascites from Cirrhosis:—

℞ Resinæ copaibæ, ʒiij;
Spiritus rectificati, ℥j;
Mucilaginis acaciæ, ʒij;
Aquæ, ad ʒxij.

Misce et fiat mistura.
A tablespoonful to be taken three times a day.
The Practitioner.

36.—For Neuralgia:—

℞ Exalgin, gr. i-ij;
Sp. chloroform, ♏x;
Aquæ, q. s. ad ℥j.

M. Sig. For one dose. Repeat every four hours.
Dr. G. G. YOUNGER.

37.—A Good Nerve Tonic in Debility.:—

℞ Liq. strychniæ, ♏v;
Liq. arsenicalis, ♏iij;
Tinct. aurantii, ♏xx;
Tinct. zingiberis, ♏x;
Sp. chloroformi, ♏x;
Aq. distill. ad ℥j.

M. For one dose. Twice daily after meals.

◆

WE regret to hear that Mr. Walter Rivington, Consulting Surgeon to the London Hospital, has during the past fortnight been confined to his house with a Pott's fracture. Fortunately the fracture is a simple one, but some weeks will have to elapse before he will be able to resume his professional duties.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, December 22nd.

The President, Dr. **Andrew J. Horne**, in the Chair.

EXHIBITS.

Dr. **Andrew J. Smith** exhibited—1. Tubes and ovaries removed for rapidly growing fibro-myoma accompanied by profuse hæmorrhage. On rotating the tumour to get left ovary, the mesentery was bruised. The patient's pulse before operation was 90. Directly after operation it fell to 36, and remained between 36 and 40 for forty-eight hours. The pulse was slow, deliberate, non-compressible, like the slow pulse of digitalis poisoning. He attributed the slow pulse to an inhibition of heart through the crushing of the mesenteric nerves. She made a good recovery. 2. A hydrosalpinx removed from a patient who, eighteen months before, had a severe attack of puerperal blood-poisoning. Her temperature before operation was 100° F. at night. The tumour was covered with very extensive adhesions. The points of interest are—The attack of puerperal fever, the presence of a cystic tube, with temperature of 100°, and still contents of cyst clear serum. Recovery of patient perfect.

Dr. W. J. **Smyly** exhibited—1. A ruptured tubal pregnancy. The patient had borne one child, and had a miscarriage—the former about eighteen months, and the latter about ten months previous. For about two months before the accident she complained of pelvic pain, a bearing down sensation, and a constant though moderate red discharge. The rupture was attended by violent pain and repeated faintings. The abdomen was opened four hours later, and the right Fallopian tube, together with the ovary and a large quantity of blood, removed. The specimen consisted of the right Fallopian tube and corresponding ovary, and showed a small crack on the posterior surface of the tube, which was distended to size of a small sausage, about half an inch from the fimbriated extremity. 2. A myoma about as large as a fœtal head, which had been embedded for about a quarter of its surface in the fundus of the uterus. The tumour having been enucleated, the cavity left was stitched up from the bottom, and the abdomen closed. The patient made a good recovery. 3. This specimen was a uterus about as large as a fœtal head infested with myomata and with cancer of the mucous membrane. The organ was removed by the mixed method. The cervix having been freed per vaginam the entire organ was extracted by abdominal section. The patient recovered. 4. Two tubes removed for pyosalpinx.

VENTRAL HERNIA FOLLOWING LAPAROTOMY.

Mr. **M'Ardle** read some notes on and brought forward some cases to support the view that the mid-stratum of the abdominal wall was the essential one to secure in completing operations for ventral hernia, or after laparotomy then continued. These will be found in another column. In the discussion that followed

Dr. W. J. **Smyly** said when a congenital umbilical hernia was cut down on, a very thick ring was found at the edge of the aponeurosis, and it was very easy to split it up with scissors. One could then turn one flap down and the other up so as to get flat surfaces of aponeurosis opposed to each other. He did two operations of the sort by the flap-splitting method of Tait, but as he had not seen the patients since he could not speak as to the ultimate result. Hernias that occurred after abdominal section were a great trouble, and brought discredit upon the operation of abdominal section. In order to avoid them one had to make the incision in a certain way and in a certain place, and stitch it with certain precautions. All these certainties were nothing more or less the uncertainties, and if different books were consulted they would see that different men laid emphasis on points totally opposed to each other. He thought it was a matter of importance not to make the incision through the linea alba, but to one side of it, so as to lay open the sheath of one rectus muscle. Good union would be the result, and especially so in cases where the tissues were stretched by large tumours. The incision should also be as high up in the abdomen as the circumstances of the operation would permit, and the incision itself should be clean-cut and not bruised. He had given up gradually the use of the pressure-clips, and he was struck lately by how little the most successful operators had used them. There were a great many different methods of suturing, but he thought the simplest method, that of Dr. Martin, the best, especially when the results were equal.

Dr. **Parsons** inquired as to the advantages gained by suturing the abdominal wound in layers.

Dr. A. J. **Smith** said that he had adopted Mr. M'Ardle's method. He thought that the layer directly over the elastic layer retracted considerably. He thought more attention should be given to the middle stratum than to the peritoneum or skin. In all the hernias he had seen it was owing to the non-approximation of this stratum. They should examine carefully each suture and see that it went through the stratum, as sometimes the superficial layer retracted.

Dr. F. W. **Kidd** thought it was admitted that often there was damage done to the tissues by the pressure forceps. It would be of interest to him to know what other means were adopted to check hæmorrhage from bleeding points.

The **President** referred to the greater likelihood of hernia occurring after suppuration in the suture track. He mentioned the case of a patient from whom he removed the appendages, and who, several months afterwards, during an attack of severe bronchitis, suffered from a considerable protrusion.

Mr. **M'Ardle** said if he had done nothing more than elicit those valuable remarks of Dr. Smyly he would be well repaid for his trouble. He said flap-splitting was the only operation where the peritoneum was fixed to the ring—it was the only one where they could have material for their sutures. He was glad to hear that the use of clips was lessened considerably, and he did not believe that a great number of sutures were necessary. With reference to Dr. Parson's question, he said the importance of the third layer of sutures was that it leaves no space in which fluid could accumulate.

Dr. A. J. **Smith** read a paper on

COLECTOMY,

Which will be found in another column.

In the discussion that followed—

Dr. W. J. **Smyly** thought the method Dr. Smith adopted with regard to the appendix a very neat one. In one case where he removed the appendix he simply pushed in the stump and stitched the peritoneum over it. While in Germany lately he had seen an appendix removed, and the operator simply tied it as if it were an ovarian pedicle, and snipped it off.

Mr. **M'Ardle** said he belived that in the peculiar movement of the appendix they saw the cause of the spasmodic pain that the patient suffered from. It was the contractions of it which caused the pain, and there were many cases of intestinal obstruction where attachment of the vermiform appendix set up either spasmodic or paralytic obstruction.

Dr. **Parsons** inquired whether Dr. Smith's statement as to tubercular ulcer of the appendix was made from a naked-eye or a microscopic examination? As far as he was aware tubercular ulcer, confined to the vermiform appendix, was comparatively rare.

Dr. A. J. **Smith**, in reply, said he found the method of amputating the appendix exceedingly quick, while it was a very secure method also. He thought the pain was due to these curious contractions of the appendix. In reply to Dr. Parsons, he said he had not yet had time to make a microscopic examination, but in the opinion of experts it was a typical tubercular ulcer, and there was no evidence of any concretion.

STRICTURE OF TRANSVERSE PORTION OF COLON.

Dr. **Doyle** exhibited a specimen of stricture of transverse portion of colon, and said the specimen was taken from an old lady who had previous attacks of enteritis and gastritis. In June last she suffered from partial intestinal obstruction, and he proposed some operative procedure which could not be carried out. On making a *post-mortem* he found both sides of the stricture distended, showing that it was not completely occluded. At the point of the stricture there was a band going towards the right side. He would account for the symptoms of intestinal obstruction occurring every week, thus—when the contents of the upper portion of the bowel passed into the descending portion, the transverse portion was weighed down, and so caused greater narrowness of the stricture, with the result that symptoms of intestinal obstruction were set up, and these passed away according as the lower colon was relieved of its contents.

Mr. M'Ardle said he had seen the case in consultation with Dr. Doyle, and at the time he diagnosed the obstruction as being in the large intestine. He said the tag prevented the passage of the vermicular contractions over that spot; consequently, emptying the bowel was brought about by stimulation of the rectum, which caused contractions of the lower part of the bowel to be set up.

The section then adjourned.

◆

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, January 4th.

The President, Mr. Malcolm Morris, in the Chair.

Dr. Sidney Phillips showed a patient with syphilitic gumma associated with a secondary eruption.

Dr. Gibbon, who only saw the legs of the patient, doubted whether the sparse pustular eruption was at all due to syphilis. It did not follow that, because a healthy-looking young woman, like the patient, had a primary sore, any and every eruption on her skin must necessarily be syphilitic. He said the supposed gumma on the leg was very different in its appearance and feel to any gumma that he had met with. It was hot, inflamed and tender and surrounded with œdematous cellular tissue. The healthy colour and appearance of the patient belied the assumption that she was suffering from secondary and tertiary syphilis. The best test for the nature of the tumour in the leg would be specific treatment.

Mr. Lockwood said the so-called gumma had run a very unusual course. When a gumma softened it was quite unusual to have so much inflammation and cellulitis. With regard to the pain in the head nearly all young females have cephalalgia at the commencement of syphilis.

Dr. Sidney Phillips replied.

Mr. C. B. Lockwood read a paper on

TRANSIENT APHASIA OCCURRING DURING THE COURSE OF SYPHILIS.

Dr. Gibbon said that he believed such cases were not uncommon and could be cured or at least much benefited by specific treatment together with a rigid abstention from alcohol. One of these cases was said to have been worse "after cigars and brandies and sodas." He had a case of recurrent aphasia due to syphilis, without any symptoms whatever of paralysis. The patient was a skilful gas-fitter in the city, and could work quite well at his trade during the attacks which always followed indulgence in alcoholic drinks. At other times he could speak slowly but correctly. These cases seem to show that the localisation of speech was not identical with any portion of the motor tract.

Dr. Leonard Guthrie believed that syphilitic aphasia was usually due to occlusion of the left sylvian artery or of its branches which supplied Broca's convolutions. Sir William Broadbent attributed such occlusion to periarteritis rather than to syphilitic endarteritis. If this were so, sudden increase of vascularity in the growth encircling the vessel might produce sudden but temporary obstruction and transient aphasia, or irritation of the blood vessel by such perivascular growth might set up passing spasm of its walls and thus produce anæmia of the speech centres and consequent aphasia. Here the pathology approached that of migraine. Mr. Lockwood negatived the idea that migraine was present in his cases mainly because headache did not accompany or follow the symptoms, but in people who suffered from migraine the premonitory symptoms, which often included aphasia, sometimes cleared up without the occurrence of headache, just as an epileptic "aura" sometimes occurred without a fit. Mr. Lockwood's second case might have been of this nature. Both his cases were those of temporary verbal amnesia rather than true aphasia, and resembled those of simple functional aphasia, to which all, especially nervous self-conscious people were subject. Functional aphasia closely resembled organic. It usually took the form of sudden forgetfulness of the names of persons, places, and things, at the most critical and inopportune moments. Sometimes just as in true aphasia, a word resembling in sound, though not in sense, was substituted for the word wanted. Familiar instances of such verbal amnesia and "malapropisms" were cited, and similar instances of functional "word-deafness" and "word-blindness" might be adduced. Such symptoms were not regarded as morbid as a rule. But it was well known that those who had had syphilis often became extremely hypochondriacal and developed syphiliphobia. In such cases the most trivial symptoms caused great alarm, being regarded by the patients as fresh proofs of the spread of the disease.

The President and Dr. Sydney Phillips also took part in the discussion.

Mr. Lockwood replied.

Mr. Watson Cheyne read a paper on

THE TREATMENT OF CANCER OF THE BREAST,

and in the first instance discussed the question of the constitutional or local origin of the disease. He pointed out that the pathology shows that sarcinomatous tumours only begin in epithelial structures, and that, therefore, where scirrhus is found in the glands, muscle, &c., after removal of the breast it cannot mean a fresh manifestation of a constitutional disease, but must imply that the attempted removal has been incomplete, and that portions have been left behind at the time of the operation and grew subsequently. He referred also to the marked increase in the percentage of cases where no recurrence has taken place since, as the result of recent researches, the operation has been made more extensive and complete. He further mentioned with regard to the subsequent appearance of cancer in the second breast, a point made much of by the supporters of the constitutional view, that it has been recently demonstrated that in some cases a communication exists between the lymphatic systems of the two breasts, and that thus it is probably a direct infection from the one first affected. He emphasised the fact that for success operations must be done early and thoroughly. As to early operation he referred to the diagnosis of cancer, and asked why, if there was any suspicion of cancer, a lump in the breast is watched. He insisted on the great importance in suspicious cases of an exploratory incision so as to settle the diagnosis at once, and pointed out that if the swelling should turn out to be inflammatory a free incision was the quickest and surest method of cure. In discussing the method of operating he stated that the old place was wrong in every particular, and said that it was of the utmost importance in all cases to remove the whole lymphatic area up to and including the axillary glands, the skin over the prominent part of the breast and over the tumour, the whole breast which is in reality very extensive, the pectoral fascia beneath, with a thin layer of the surface of the muscle, the fat and fascia leading to the axilla, and the whole of the glands and fat in the axilla should be dissected away in all cases. Mr. Cheyne then referred to his results, and stated that of the first twenty cases operated on in this way during 1890, 1891, and 1892, fourteen to his knowledge had remained well and four had recurred. Taking only those done in 1890 and 1891, that is to say more than two years ago, fifteen in number, ten remained well, four had recurred, and he had not yet heard from one. This gave a percentage of recovery lasting two years or more, of sixty-six per cent., and as recurrences generally take place in from six to eighteen months there was a great probability that a considerable proportion of these ten cases would remain permanently well. He did not assert that this was at all the ultimate probable percentage of success, but it indicated a greatly better prospect than by the ordinary imperfect operation. He did not think that allowing for accidents, intercurrent diseases, &c., the mortality of the complete operation might be more than two to four per cent. In conclusion, he referred to the cases suitable for operation, and those in which operation was contra-indicated.

Mr. Lockwood quite agreed with Mr. Watson Cheyne that operations upon cancer of the breast ought to include a thorough removal of the whole gland, subpectoral fascia, and axillary lymphatic glands and fat. He never operated without opening the axilla. Doctors were not always to blame for delay because women shrank from such a mutilation as removal of the breast.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Thursday, December 21st, 1893.

The President, Mr. Richard Favell, M.R.C.S., in the Chair.

Specimens.

Dr. Wilkinson showed for Dr. Laver a specimen of sarcoma of the uterus, and gave an account of the case. The specimen had been obtained by vaginal hysterectomy performed by Dr. Laver. The patient died 2½ months later from extensive secondary deposit in the lungs. Attention was drawn (1) to the rarity of sarcoma in the uterus, only 81 cases having been recorded; (2) to the similarity of the temperature chart with that of a case of pyæmia. Microscopic sections of the growths were exhibited.

Dr. Burgess showed—(1) a heart from a boy of 15 years in which the membranous septum between the ventricles was not closed, and the aorta sprung from the right ventricle; (2) the large bowel from a case of severe ulcerative colitis.

The President showed a specimen of fibroma of labium.

Dr. Knox showed a specimen of congenital atresia of the small intestine. There was a complete interruption in the continuity of the bowel about the junction of the jejunum and ilium, the gut above the malformation being dilated and hypertrophied, that below small.

Case of Supernumerary Mamma.—Dr. Arthur Hall showed a case of a woman who had been attending at the Public Hospital for gastric trouble at the climacteric, and happened to mention that she had a third breast which secreted milk during each period of lactation, except that which followed after the birth of the first child. On examination a well-formed nipple was found under the left breast situated in the nipple line, four inches below the left nipple and four inches to the left of the middle line, lying over the end of the 8th left costal cartilage. No gland could be felt connected with it. The nipple measured 1-6th inch in diameter, with a transverse slit at the summit, and had an areola of about ¼ inch round it. Dr. Hall then alluded shortly to the literature of recorded cases, and showed that, whereas accessory nipples were by no means uncommon, if carefully sought for, yet a physiologically active accessory breast was distinctly rare. He also discussed the question of their being remains of an ancestral type, and whilst admitting that such was not altogether improbable, was not satisfied that such an explanation applied to all cases.

Dr. Hall also showed the following:—

1. *A Case of Lupus Erythematosus* in a woman, æt. 60, which began 5½ years ago, on returning from a visit to the seaside. It began with swelling of the nose, cheeks, and eyes, which was very irritable. This gradually subsided, but left the present condition. The whole face above the naso-labial folds was more or less affected, also the scalp in parts.

2. *A Case of Adenia, or Chronic Hodgkins' Disease*, in a young woman, æt. 24, in which the cervical and axillary glands were enlarged, especially in the right axilla, where there was one the size of an orange. The condition had lasted some time, and there was some anæmia.

3. *A Case of Cerebellar Tumour* in a boy, æt. 9. He had begun, six months before admission to the hospital, with "brain fever"; this was followed a few weeks after by difficulty of walking, headache, and vomiting. The gait on admission in February, 1893, was very curious, the boy always falling over towards the left and backwards; it resembled the movement of a man balancing on a tight rope with a weight fixed to the back and left side. During his stay in the hospital, with the ophthalmoscope, signs of optic atrophy were observed, and the field of vision was found to be very small. The vomiting ceased, and the headache was less severe. He left the hospital in the spring of 1893, and was not seen again until October, 1893, when his difficulty of walking had quite disappeared and the field of vision largely increased in size. He still suffered from some headache and had occasional "fits."

◆

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held January 11th.

The President, Mr. F. Bowreman Jessett, F.R.C.S., in the Chair.

Annual Meeting.

After the election of office-bearers for the ensuing year —a list of whom will be found under the heading of "Medical News"—Dr. Schacht read for Dr. Benington the notes of a case of

RUPTURED TUBAL GESTATION

operated on 18 months previously for a similar condition.

[This paper we hope to publish in an early number.]

Dr. Mansell Moullin agreed with Dr. Benington's view that when an operation was undertaken for the removal of a ruptured tube, the appendages of the other side ought to be removed at the same time. He had himself related a similar case before the Society, and more recently at the West London Hospital he had adopted the procedure of removing the appendages of the other side, though they were not diseased. Dr. Mansell-Moullin referred to Lawson Tait's view that ectopic gestation was due to the loss of cilia in the Fallopian tube, whereby the ovum was impeded in its progress; but pointed out that in order that gestation should occur at all, it was necessary that the tube should be at least partially healthy, for otherwise the ovum could not be got into it.

Dr. Routh said that he was not aware that the loss of cilia had been demonstrated anatomically. If they were destroyed by inflammation, how was it that the spermatozoa were not destroyed; and secondly, that tubal pregnancy did not occur bilaterally every time? Till these questions could be answered, he thought the theory could not be proved.

Dr. Travers said he had a patient walking about whose case might throw some light on the subject. Only twice during her married life was she pregnant, at an interval of six years. Each time she had symptoms of ruptured tube, with collapse. The symptoms pointed to rupture first on one side, then on the other. He did not operate on the second occasion because she did so well without on the first, and though the case caused him much anxiety each time, she made a good recovery.

Dr. Schacht supported Dr. Benington's suggestion that the specimen should be referred to a committee. He had a case only a few weeks before, but did not remove the healthy ovary. He thought it was contra-indicated as long as we do not know the cause of the condition. It was agreed that a committee should be nominated to report on the specimen, consisting of Drs. Benington, Eden, and Shaw-Mackenzie.

FIBROID OF THE UTERUS.

Dr. Heywood Smith showed a specimen of fibroid of the uterus, removed by vaginal hysterectomy. The patient, æt. 38, had been a widow eleven years. In November, 1892, she was admitted to Warrington Lodge, when a flat polypus, 2 inches long, was cut away. She left, relieved, in the following January. In December, 1893, she was re-admitted, having suffered from severe pain for some months, which incapacitated her from earning her living. Vaginal hysterectomy was accomplished with some difficulty as the patient was a multipara. The appendages were removed with the uterus. He believed this was the first case in England of vaginal hysterectomy for fibroids, but Doyen, of Rheims, had published an account of fifty-three cases, with four deaths (see *British Medical Journal*, December, 23rd, 1893), and the procedure was advocated by Dr. Montgomery in the *Amer. Jour. of Obst.* for November, 1893. The patient has made a good recovery.

Dr. Napier asked whether there had been much hæmorrhage in this case, and whether Dr. Heywood Smith regarded vaginal hysterectomy as a less serious measur than oöphorectomy for this condition; it seemed to him that this was the kind of case in which the latter operation was indicated.

Dr. Bantock presumed that Dr. Heywood Smith did not advise hysterectomy as the usual treatment in these cases; he agreed with Dr. Napier that oöphorectomy involved less risk, and so it was not generally advisable to expose the patient to the danger of the graver operation.

Mr. Jessett showed a uterus studded all over with myomata. It was removed for pain. The os was thickened and the cervix hard, and it was a question whether there was commencing malignant disease. The left ovary and tube were also much diseased. The patient was doing well. With reference to Dr. Heywood Smith's specimen, he saw the case with him, and, like him, advised delay, but the patient, on account of the pain, urgently desired operation. As the pain was probably due to stretching of the broad ligament, it was doubtful whether oöphorectomy would have met the case.

Dr. Heywood Smith, in reply, said that hæmorrhage had not been increasing, and it was a fair criticism to ask why he operated. He judged from careful examination that the tumour was in the uterine tissue itself, and so thought that oöphorectomy would not relieve the pain. This, combined with the fact mentioned by the President, led him to do hysterectomy. He thought, however, that every case must be considered and treated on its own merits.

PRESIDENT'S ADDRESS.

The President then delivered a Valedictory Address, in which, after complimenting the Society on their choice of a new President (Dr. Savage, of Birmingham), he gave a succinct and critical review of the work accomplished during the year.

The meeting closed with a cordial vote to Mr. Jessett for his ability and courtesy during his year's office as President, and to the Hon. Treasurer and Secretaries for their services to the Society.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, Jan. 17th.

Dr. T. S. Clouston, President, in the Chair.

CASES TREATED WITH THYROID EXTRACT.

Dr. Byrom Bramwell exhibited three cases of skin disease treated with thyroid extract, all of whom he had already shown to the Society—one case of psoriasis and two of lupus vulgaris. The three were improving greatly under treatment. He also showed a remarkable case of ichthyosis in a female adult. When born her skin was said to be normal, but on the second day the skin began to get horny, the only parts unaffected being the palms of the hands, the soles of the feet, and the face. Now, the same parts are still clear, but the rest of the body is covered with a thick, grey, horny cuticle with an indescribable appearance. Under treatment with thyroid extract the affected epidermis had in places began to fall off, leaving comparatively healthy tissue beneath. This had never happened under treatment before. She was, however, suffering from some abscesses in the back, probably an outcome of the treatment.

Dr. W. Stewart showed a man who by a fall down into the hold of a ship dislocated his foot. The dislocation was compound sub-astragaloid in nature. He made a satisfactory recovery.

Dr. Allan Jamieson showed a woman with a form of lupus erythematosus resembling the telangiectic variety described by Crocker. The disease had commenced on one cheek eleven years ago; both cheeks were now affected.

Dr. John Thomson handed round several photographs showing the progress of a case of cretinism under treatment with thyroid extract. The patient had been under treatment for 12 months, had grown 4½ inches, and got eight permanent teeth.

Dr. Herbert Littlejohn showed some productions in two cases of very determined suicide, and Dr. Bruce a cholesteatoma which was found *post mortem* above the choroid plexus of the fourth ventricle. The only symptom noticed during life was some giddiness.

Dr. James McKenzie, of Burnley, read a paper on

THE SIGNIFICANCE OF PULSATIONS IN THE VEINS AND IN THE LIVER.

Dilatation of the right side of the heart was frequently accompanied by pulsation in the veins of the neck, due to incompetence of the tricuspid valve. Up to the present, owing probably to imperfect instruments, no reliable tracings had been made of this pulsation, especially with regard to its synchronicity with the arterial pulse or apex beat. Dr. McKenzie proceeded by means of a Dudgeon's sphygmograph, to which he attached an additional pen connected with a cup which could be placed over a vein. The arterial and venous pulse could then be easily obtained on the same piece of paper. In recording the liver pulse a larger wooden cup was used. Careful examination of the tracing obtained from the internal jugular in cases of tricuspid incompetence showed that there were two types, the auricular and the ventricular types. In the first the chief elevation occurred during the auricular systole, and therefore while the ventricle was in diastole. Diastole of the auricle then occurred, the pressure fell, although at that moment the ventricle was in systole. The wave caused by the systole of the right ventricle had first to fill the cavity of the right auricle before it could take effect on the great veins. The wave in the veins was therefore delayed until the end of the ventricular systole. A secondary wave in the tracing was due to the additional pressure caused by the closure of the pulmonary valves. In the ventricular type the rise in the venous tracing was coincident with the carotid pulse when the auricle was almost paralysed. The existence of a small secondary wave just after the chief venous curve had caused a great deal of speculation previously; it was due to the impact of the carotid pulse below the vein and occurred at that moment for the reason above stated. In some cases of tricuspid incompetence in which there were intermissions in the radial pulse or marked irregularity he had been able to obtain perfectly regular tracings from the veins, showing that the main origin of this pulse was not ventricular but auricular. In fact, the venous wave was larger when the left ventricle missed a beat, and naturally, as there was an excess of blood in the venous system. In the pulsus trigeminus again the venous pulse remained normal. All these facts could only be explained, he thought, in the way which he had pointed out, and if so, were of value in indicating exactly what occurred in cases of incompetence of the tricuspid valve, a lesion which often existed without the presence of a murmur being discoverable.

Dr. G. A. Gibson paid a warm tribute to the extreme value of Dr. McKenzie's paper. He said that Friedriech's work on the same subject had been explicitly accepted for so many years that when he made some researches into the matter himself he had not questioned Friedreich's conclusions. Dr. McKenzie's results also showed how valuable the graphic method was when rightly applied. Roy's explanations of the pulsus trigeminus must now have received its *quietus*.

Dr. Byrom Bramwell and Dr. Graham Brown spoke.

Dr. Noel Paton had listened with very great interest to the paper, especially to that part relating to the action of the auricle apart from the ventricle. He was not quite convinced about the explanation with regard to the small wave said to be caused by the pulsation of the carotid artery.

Dr. McKenzie, replying, said that the small wave referred to was certainly due to the conduction of the beat of the carotid through the vein, for in the liver pulse it did not occur unless the tracing was taken just over the aorta. The trigeminal pulse had been called the vagus pulse, but that was an error, for stimulation of the vagus first affected the auricle, while the auricular pulse, as he had shown, went on regularly.

Dr. Byrom Bramwell read some notes on a case of

CANCER OF THE SPLEEN AND OTHER ORGANS.

The patient, female, forty years old, was admitted to the Infirmary with multiple tumours of each breast. In 1890 a growth of the size of a walnut had been discovered in the right breast below the nipple. This had not increased in size, but numerous other nodules had appeared in both breasts. These were never tender. In time her fingers became numb, she saw double, then the sight of the right eye was lost. She had no headache, vomiting, or giddiness. On admission the mammæ were crowded with small nodules, numbers of which ran out in chains under the skin in all directions. The liver and spleen were large, but not tender; the red blood corpuscles were 3,430,000 in number, the hæmoglobin 64 per cent. Two months later the number of corpuscles had fallen to 2,410,000, hæmoglobin to 46 per cent. Other parts of the body became affected before death. At the autopsy cancerous growths were found in nearly all the organs, viz., in the mammæ, subcutaneous tissue, mesentery, peritoneum, liver, spleen, ovaries, vagina, uterus, sciatic nerves, kidneys, suprarenal capsules, pancreas, stomach, pericardium, pleuræ, dura mater, spinal meninges, one femur, and in the periosteum of the ribs. None were found in the lungs, the brain, or the thyroid gland. The liver and spleen were large, smooth, painless, and stony hard.

Dr. **Leith** described the microscopic appearances of the growths. They were mostly small-celled, the edges very indistinct in some of the organs, while the lymphatics were all choked. The cancer seemed to have spread by way of the lymphatics.

Dr. **Stiles** said that what seemed to be the primary tumour in the right mamma was in reality a simple fibroma. He thought the disease had been scattered through the body by the blood stream.

Dr. **Bruce** had not seen the spleen affected in this way before. He also thought the cancer must have been conveyed by the blood setting up the scattered nodules by means of emboli. As the capillaries of the lungs were larger than those of the other organs the immunity of the lungs could thus be explained. He was not surprised to find that, although the adrenals were much disorganised by the cancer, yet no symptoms of Addison's disease resulted. The affection of the adrenals must be tubercular to cause that disease.

Dr. **Russell** corroborated this last statement. Destruction even of the suprarenal bodies by cancer did not produce Addison's disease.

Dr. **Bramwell** replied.

France.

[FROM OUR OWN CORRESPONDENT.

PARIS, Jan. 19th.

GASTRO-ENTEROSTOMY.

The operation of Voelfler was almost accidentally innovated by this surgeon in 1881, when assisting Prof. Billroth in the course of a laparotomy for cancer of the pylorus. Finding that the tumour was too large and too adherent to be extirpated totally, he practised from necessity gastro-enterostomy, that is to say, he created a communication between the stomach and the first fold of the jejunum. Success followed, and the operation gained rapidly favour with the German surgeons, more than one hundred cases being already published.

In France Voelfler's operation has not been practised so largely, nor as much as it ought to be; yet surgeons are ready to admit that this method of treating cancer of the pylorus is justified by the results it gives. Guinard, Jaboulay, and Doyen have published cases of anastomosis of the gastric organ and the jejunum for stenosis of the pylorus from cancer, in which the consequences were just as satisfactory as any reported by their Teutonic *confrères*, and more than once recently has the subject been discussed at the Société de Chirurgie.

The details of the two most recent cases furnished to me by a brilliant provincial operator, Dr. Blanc, are interesting enough to be reported.

Case 1.—A—— Pierre, æt. 45. This patient, a confirmed drunkard, was admitted into the hospital on the 15th July last for cancer of the pylorus, but the milk diet to which he was submitted produced such a good effect on him that it was thought he was suffering only from chronic gastritis due to excess of alcohol. The man left the hospital to return to his work, but in ten days he returned, emaciated, and in a very weak condition. He felt no pain, but vomited all he took. Examination of the gastric region revealed no tumour, nor could any glands be found in the axilla or at the base of the neck. The diagnosis made was—alcoholic gastritis with cicatricial stricture of the pylorus. The obstruction increasing and the patient dying of hunger and thirst, an operation was proposed and gladly accepted. Dr. Blanc traced an incision from the xiphoid cartilage to one inch below the umbilicus. The stomach being drawn out, the pylorus was found to be invaded by a hard tumour of an evident cancerous nature; its volume was so great that it was not possible to think of performing pylorectomy. Having raised the omentum, the operator passed in his hand, and gliding it down by the edge of the duodenum until the first portion of the jejunum was reached, he drew it out, and adapting a fold of it to a similar one in the stomach, and a slit of an inch in length having been practised in both folds, the two organs were sutured together; the whole was returned into the abdomen and the primary wound closed. All that day ice was given, and the three following, iced milk; later, broth, milk, and an egg was permitted, but from time to time the patient vomited. However, since the 2nd October all this has ceased, the man eats very well farinaceous food, has gained rapidly in flesh, weighing twenty-two pounds more than at the time of the operation, and no one would now imagine that he had ever had cancer of the stomach.

Case 2.—Ch. André, æt. 38, miner, and also addicted to alcohol, entered the hospital in August last suffering from intense pain in the gastric region, especially after taking food. He vomited incessantly. The stomach was found to be dilated and was evidently the seat of a malignant growth. The patient was very emaciated. An operation was proposed and gladly accepted. On the 30th September the stomach was opened and found to be largely dilated. Near the pylorus the cancer was discovered and appeared to be very extensive. The stomach was put into communication with the jejunum as in the first case and the wound closed.

The first day the man vomited freely in spite of the ice given him, but soon he was able to take milk, and by the 20th day after the operation he regained 10 lbs. in weight. He has been seen frequently since he left the hospital, and is getting on admirably in spite of the cancerous growth.

Gastro-enterectomy, says Dr. Blanc, is a benign operation and affords considerable relief to the patient. Further, the malignant tumour not only does not develop rapidly after the operation, but frequently retrocedes, and the patient's life can be prolonged for a considerable period.

◆

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan 19th.

THE PROFESSORSHIP OF CHILDREN'S DISEASES.

The Chair of Children's Diseases rendered vacant by the retirement of the veteran Professor Herroch has been filled at last by the appointment of Professor Heubner, of Leipsic. On the chair falling vacant the Faculty placed Professor Heubner's name first on the list submitted to the Cultus Minister for the appointment. He was at once offered the post, but could not at first see his way to accept of it, one reason of this state of doubt being that at Leipsic he was ordinary professor, whilst in Berlin the position is one of extraordinary professor only. He first made the request that the extraordinary professorship should be converted into an ordinary, but this was refused, as it had been previously to Professor Herroch. He finally, however, made the decision to accept the chair as it stands. He is now 51 years of age. He has hitherto worked only in Leipsic; from 1862 to 1867 as a student, and after a short period of study at Vienna he returned to Leipsic, where he became assistant to Wunderlich in 1868, and Privat Docent in medicine in 1869.

During the Franco-German War Dr. Heubner collected observations on dysentery and the diseases affecting soldiers in consequence of over-exertion with knapsacks and arms, and published a contribution on the subjects.

The extraordinary professorship of Medical Jurisprudence is also vacant since the death of Professor Liman, since which time the post has been provisionally filled by Privat Docent Dr. Strassmann. It appears to be the intention not to fill the post permanently, at least for the present. A few advancements are announced for the new year. Amongst them Drs. Martin and Veit, well known gynæcologists, have become titular professors, as well as the dermatologist, Dr. Lassar, and Dr. Remak, the neurologist.

STRUMA CONGENITA.

At the last meeting of the Medical Society Hr. Schimmelbusch related a case of the above. On November 22nd last a child, an hour and a half old, was admitted into Von Bergmann's klinik suffering from extreme difficulty of breathing. The obstruction was caused by a large tumour on the anterior aspect of the neck which compressed the larynx like a struma. The tumour reached from the chin to the sternum, and covered nearly the whole front of the neck; when the tumour was seized and drawn forward the breathing became easier. The speaker had in all such cases in recent times tried to avoid tracheotomy and bring about a radical cure by removing the tumour. The tumour was accordingly removed. On section it proved to be larger than a hen's egg, and to consist of solid tissue in which a large number of cysts were scattered. It showed nucleated connective tissue with numerous epithelial tracts and cylinder epithelium; there were also patches of cartilage. He took the tumour to be a congenital struma. Such tumours were also met with in animals, such as horses, dogs, goats, &c. Congenital struma was rather frequent in families in which the disease was hereditary. Denne had met with 43 cases in a total of 642 cases of struma. The prognosis depended on the size of the tumour. At the time of reporting the child was two weeks old.

Professor Virchow said that his impression was the growth was not a struma, but perhaps a tumour something approaching a thyroid gland developed in an unusual way. A tumour that contained epithelium and cartilage was far removed from that called struma; it rather resembled the mediastinal tumours that arose from the dispersed elements of the bronchi. He would rather call the tumour a keratoma.

THE TREATMENT OF VARICOSE ULCERS OF THE LEG.

At the meeting of the Dermatological Society of the 5th ult. Hr. O. Rosenthal gave an address on this subject. The speaker said that since the publications of Unna he had made use of the zinc gelatine dressing in a number of cases with success. It was soon evident, however, that in cases where the secretion from the ulcer was free a modification of the procedure was necessary. Retention of secretion readily took place under the dressings with consecutive irritation of the skin, rendering necessary an expensive and time-consuming frequent change of dressing. For this reason the speaker had introduced a fenestrated bandage. He covered the ulcers with watch-glasses and passed by these whilst putting on the bandages. The bandages had then the zinc gelatine rubbed in. In order to protect the bandage from ointments or other applications to the ulcers the margins was painted round with photoxyllin. The bandage in this way answered the requirements as to compression of the limb and assistance to the circulation, whilst the treatment of the ulcers themselves could be varied to suit each case. The dressing of the ulcer could be renewed at pleasure, and the bandage would remain in position from two to six weeks.

Hr. Kecrewski thought the zinc gelatine dressing did excellent service in protecting against recurrence of the trouble. Large ulcers generally did not heal under the zinc gelatine dressing, and in the case of ulcers the size of the hand the fenestrated bandage was not practicable. The main object in the treatment of ulcus cruris was the procuring of an aseptic wound surface. He therefore dressed all cases with a daily antiseptic application of acetate of alumina. The most rational treatment of ulcer of the foot was the surgical. In numerous cases he had extirpated the varicose veins and transplanted healthy skin on the ulcers themselves. The saphena magna vein even might be ligatured and the patient not be confined to bed. The radical operation was simple, not very dangerous, and allowed complete recovery to the patient in three to four weeks. The speaker, in conclusion, referred to cases that had remained well after three and four years.

Hr. Rosenthal, in reply, said that the treatment of the ulcers by antiseptics had often to be given up on account of the great irritation of the skin caused by them.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Jan. 16th.

BLOOD PRESSURE.

AT the meeting of the "Gesellschaft" Federn gave a long account of his experiments in the different forms of hæmatic pressure. The most common are those arising from resistance, met with in the peripheral system. It was customary among the older physiologists to attribute high pressure to the action of the heart, but recent investigation has located the true cause to resistance. Occasional high pressure may be of little moment in the physiological economy, but where it becomes chronic or continuous, dangerous consequences will inevitably ensue. The normal blood pressure ranges from 80 to 90 mm. of mercury in the male and 80 to 100 in the female. Mechanical resistance from tumours, œdema, irritating the vaso-constrictors, &c., have been utilised in his experiments, and he concludes that the splanchnic nerve is one of the principal agents in producing the elevation of pressure; hence the logical results he obtained were frequent high pressure from bowel disturbance. An abnormal high pressure can be maintained for a considerable time by a healthy individual, but any weak organ must eventually suffer. The resistance produced in young persons is usually due to nervous disorders, while in the aged it arises more frequently from asthma. The neurasthenic symptoms will disappear as soon as the hæmatic pressure is reduced. Valvular insufficiency will raise the blood pressure, but this is always a relative factor. It is now shown to be a physiological fallacy that arterial sclerosis produces arterial tension. The elastic artery only modifies the pulsation, but has no effect on the hæmatic tension. The pressure will be found as high in a rigid vessel as in an elastic one in the same system. The splanchnic nerve is the common source irritated in chronic cases by partial atrophy of the bowel, but in the acute by constipation. The latter may be treated effectually by purgative medicines, but the former will require faradisation of the bowel. Digitalis should only be administered where there is insufficiency of valves with lowered pressure, or in high pressure if periculum in mora be imminent combined with purgatives.

INTUBATION PHANTOM.

Schlossarek showed several phantom throats for intubation, which gave rise to a discussion on the principle of intubation in diphtheria.

Dr. Grossman remarked that this treatment, recommended by Dweyer, was no new application, as twenty years ago catheters were applied in diphtheritic stenosis in Vienna. As to the tubage treatment, there were now many adherents, but there were also strong objections raised against the introduction of a tube into a canal so much inflamed. It is possible that after the introduction relief may be obtained for a short period, but it cannot be denied that serious consequences often result from the mechanical separation of the epithelial covering and mechanical injury to the internal walls.

Dr. Isenschutz contended that excellent results had been obtained by the help of tubage, and considered it a great advance in treatment over tracheotomy.

Widerhofer also supported the tubage treatment, saying that it had increased the recoveries 15 or 20 per cent. The tubes could be so easily inserted in children that he could not at the present time conceive how he could treat croup or diphtheria without their use.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

SUPRA-VAGINAL HYSTERECTOMY BY SCHROEDER'S METHOD.—Mr. ANDERSON operated on a married woman, æt. 35, who was admitted with a tumour in the lower part of the abdomen. The patient stated that her mother had been operated on for a tumour in the same region. In the present instance the swelling had been noticed two years before admission, and the woman had since suffered from menorrhagia associated at first with but little pain, but since the tumour had reached larger dimensions she had experienced dragging sensations which had interfered with her domestic work. On examination a central tumour was found in the lower part of the abdomen extending to within an inch of the umbilicus, smooth, hard, and rounded. On each side was a thick cord-like structure which passed outwards towards the brim of the pelvis. On internal examination the uterine canal was discovered to be about four inches in length and displaced forwards, apparently by a growth in the posterior wall of the organ. It was diagnosed as an intramural myoma. The operation was commenced by an incision in the linea alba about three and a half inches in length, exposing a tumour which was seen to comprise the enlarged uterus with its appendages; on drawing it from the abdomen the cervix was found unaffected, forming a distinct pedicle. The ovarian vessels were ligatured in the infundibulo-pelvic ligaments, the uterine vessels on each side of the cervix; the broad ligaments were divided, leaving the appendages attached to the uterus; an incision was then made through the neck near its junction with the body in such a way as to leave anterior and posterior flaps, and the whole mass removed from the abdomen. The operation so far was almost entirely bloodless, only two or three small vessels in the broad ligaments requiring ligature. The cavity of the cervix being recognised, the edges of the mucous membrane were united by catgut sutures, a second set of buried silk sutures was then passed through the thickness of the stump on each side in such a way as to unite the opposed surfaces of the two flaps; lastly, the peritoneal edges were brought together by a row of Lembert's sutures and the abdomen closed, deep catgut sutures being applied to the peritoneum. No drainage tube was employed. Mr. Anderson remarked that Schroeder's operation was more in accordance with the principles of modern surgery than any other method, as he thought that in the more simple cases its mortality should only be a little higher than that of ovariotomy. He considered that the preliminary ligature of the vessels reduces loss of blood to a minimum, and the careful suturing of the peritoneum renders the chance of infection from the cervical cavity very unlikely to occur. The abdominal incision, he said, would close by first intention, and the patient, he hoped, would be practically well by the end of a fortnight. Some cases, he pointed out, presented difficulties not met with in the one under consideration: the tumour might encroach on the cervix in such a way as to render it difficult to secure a satisfactory pedicle; in such a case the growth must be carefully enucleated as a preliminary measure, and the risks of the operation are of course somewhat increased, but in the hands of Schroeder very satisfactory results have been secured even in the most complicated cases.

UNIVERSITY COLLEGE HOSPITAL.

CLEFT PALATE.—Mr. BARKER said the case he was about to operate on was interesting to him personally, as it was the second time of operation. Some months ago he had closed the cleft in the palate in the ordinary way, and everything had gone on well, but unfortunately the friends of the little patient had smuggled some grapes into the hospital, and the child in sucking them had torn everything away. He had allowed some months to elapse so that the tissues might regain their normal condition, and now he was about to operate again. He laid stress on the importance in paring the edges of the cleft, of taking away the strip of mucous membrane in one piece, as the surgeon can then be certain that no part remains unfreshened; he thought too it was of great consequence to free the palate from the bone all round so that the two flaps hang down and come together. After these steps had been carried out he first put in five silver stitches with T. Smith's needle, and then found it necessary to put in four more to make everything secure, the tissues being of course much tougher than at the first operation. He made no lateral incisions on this occasion, as they were, he said, not necessary. Mr. Barker remarked that, as the patients had to be starved for a time after the operation, he did not like performing staphyloraphy on very young children, not till the patient was seven or eight (the one under consideration was seven). Another reason he pointed out was that for very young children the loss of even a small quantity of blood was a serious matter, and they were also prone to suffer very much from blood getting into the lungs. He dwelt on the importance of having the mouth, throat, and nose thoroughly cleansed before the beginning of the operation.

Dr. DUDLEY BUXTON called attention to the fact of the little patient only having absorbed two drachms of chloroform during the operation, which lasted half-an-hour; much of this too was really not absorbed at all, the mouth being so widely open all the time. He said as little as possible of the anæsthetic should be given in these cases, for it was most important that the patient should not be sick.

THE CONTROL OF HOSPITAL PATIENTS.

THE personal control of hospital inmates is an important question, not only on the score of discipline and of the avoidance of possible scandals, but also in the interests of patients themselves. By control we here mean, for present purposes, not somuch the absolute power of enforcing discipline as of preventing a patient from leaving the hospital when such a course is evidently hazardous and undesirable. It may be at once admitted that the power of compulsory detention is not recognised in the hospitals of Great Britain. A principle of the kind was to some extent adopted for a few years while the Contagious Diseases Act was in force—that is to say, in certain definite districts women of loose life, proved to be suffering from venereal disease, could be detained under medical restraint until cured. That position, defensible from the standpoint of the benefit of the individual no less than that of the community, was unhappily, in the opinion of the majority of medical men, reversed by the action of a small section of sentimentalists. To a much smaller extent a similar principle is involved in the detention of patients in our infectious hospitals. In the latter institutions, however, the great and fundamental difference exists that the patients submit themselves voluntarily to treatment, which is only granted on certain definite conditions. It is this conditional element which affords the key to a solution of the question of hospital detention, and it will be referred to again later on in the course of this article. Our attention has been drawn to this subject by an inquest lately held at Guy's Hospital. A man was brought thither suffering from a compound comminuted fracture of the leg. After seven days' stay in the hospital he determined upon leaving, and persisted in that suicidal intention notwithstanding all persuasion to the contrary. As it turned out, he died suddenly, almost in the act of leaving the hospital, for whilst being driven away in a cab he had a fit, and on being brought back was found to be dead. The point of interest, so far as we are now concerned, was raised by a juryman, who asked if it were right on the part of the hospital authorities to allow the deceased to leave, looking at his serious condition. To this the house surgeon very properly remarked that a hospital was not a prison, and if a sane person persisted in wishing to go out he could not be prevented. There can be no doubt whatever that to restrain forcibly a patient who had been unconditionally admitted would be to commit an illegal act. The mere fact that the patient's outgoing would almost necessarily involve his death, as in the case at Guy's, would not warrant detention against his will. But the instance quoted, some of our readers may exclaim, is exceptional, and there is no need to legislate for exceptional cases. On the contrary, we venture to assert that the persistence of patients in leaving hospital when unfit is of constant and common occurrence. Everyone who is familiar with the inner life of our great voluntary hospitals knows well enough that many a patient leaves under these circumstances. Some fancied slight, or it may be, in exceptional cases, some real grievance, some imaginary injustice, some unreasonable objection to the routine of food, ventilation or clothing, and next day an empty bed marks the disappearance of the malcontent. Although this sort of thing is not uncommon in the voluntary institutions, it goes on day after day to an unlimited extent in the Poor-law infirmaries. In the latter special conditions obtain. The patients are drawn from a class particularly impatient of control; the discipline is of the strictest, while the fare and other appointments are not infrequently of a mean and sordid nature. It now remains to inquire if any remedy can be found to prevent patients leaving the wards before they are properly cured, and, as already pointed out, we believe that such a means is attainable by making admission conditional. In not a few institutions a stipulation is made that in case of death the authorities shall have the right, if deemed advisable, of making a *post mortem* examination. There is no apparent reason why this agreement should not be extended so as to render it impossible for the patient to endanger or even sacrifice his life by premature departure from hospital. Poor-law infirmaries might surely apply to the Legislature for powers of reasonable control in the same direction, and ask to be allowed to retain patients, forcibly if need be, who are admitted for treatment. There can be no doubt whatever, except in the minds of sentimental guardians, that the medical officers of Poor-law infirmaries should have an absolute right of performing a *post mortem* on deceased patients. At present the value of the good work that is being done in many of these places is greatly lessened by the absence of such an examination, and this loss would be more than ever felt if these institutions are thrown open to future generations of students. Another point which should be alluded to by way of caution is that a patient who insists on going away when he has been duly warned of the extreme danger he will thereby incur can hardly be regarded as a morally sane and responsible man. In addition to the well-recognised condition of traumatic delirium there are many minor degrees of loss of moral control, induced by sickness or accident, which may render a patient irresponsible. Nor can any ordinary house surgeon be reasonably expected to recognise these obscure phases of perverted brain action. In such a case the medical attendants at the hospital are bound to think and act for the patient. The hospital authorities would not dream of allowing a man to eat and drink improperly, to prowl about the grounds at night, or to perform any other outrageous act endangering his own safety. Then why should they allow him to ride off in a cab simply because he insists upon going, although it is humanly certain he is flying straight into the jaws of death? In the Guy's Hospital case one would be inclined to say *primâ facie* that a man could not be called sane if he insisted on going home seven days after sustaining a "compound comminuted fracture of the leg." It would be well if some test case could be brought into court so as to establish a precedent for future guidance in similar difficult and trying circumstances. We want a clear definition of what should constitute "reasonable control" of patients, and how far hospital authorities would be justified in enforcing such control.

◆

THE INTRA-UTERINE LIFE.

THE numerous readers of *The Asclepiad* have long been accustomed to seek and find in its pages inspiration of the highest value, both in stimulating thought and in directing practice. Many, indeed, have learned to await the appearance of each new number of this scholarly periodical with eager expectancy of finding within its covers, in the pregnant utterances of its learned author, that spur to their own intellectual activity that is ever afforded by the well-considered and matured experience so characteristic of all Sir Benjamin Richardson's literary work. How much the younger generation of practitioners owe to him in this connection even they themselves can scarcely be fully conscious of; but of the fact itself there can be no questioning; and in its truth is contained assuredly most gracious testimony to the invaluable worth of the master's own labours in the cause that he has made so peculiarly his life's pursuit, the preservation of the people's health. In the current issue of *The Asclepiad* one short article, introduced among the *opuscula practica*, possesses an importance far more reaching than its brevity might be assumed to indicate, inasmuch as it raises questions which well deserve the most anxious and detailed consideration that can be given to them. It deals with the subject of the impressions received by the growing being during the period of its existence within the mother's womb; and it is calculated to awaken thoughts that could never have been excited so forcibly and with such prospect of advantage as at the present time. Sir Benjamin Richardson points out that the intra-uterine life includes two stages, the embryonic and the fœtal, and he advocates the view that in point of importance to the developing organism, the first named, or embryonic stage, is far beyond the second or fœtal, in which, with all its bodily organs completely constituted, it is able to assume an independency of organic functions impossible to it while, as an embryo, it is immediately dependent on its mother. This aspect of the matter is one that it is not customary to bear in mind in ordinary educational work; but that it has claims to the most careful consideration, a little reflection must sufficiently convince. It forces the conviction that the ultimate tendencies of the individual, the type and character of the offspring, the structural perfection of its tissues also, are intimately dependent on the mother's condition and surroundings at this primary period of pregnancy, and that according to the favourable nature or otherwise of these it will be definitely determined in what direction, for good or evil, the development of the child will tend. In the words of our author, "what" the mother "eats and drinks, what exercise she takes, what sleep she receives, what clothes she wears, what surrounding states or conditions affect her mental sphere, all tell on that newly-formed entity the coming child; the build, the quality, nay the sex may be determined here, it is the genesis of the new existence." The concluding sentence of this passage, while it fittingly emphasises the gravity of the several principles it helps to expound, may be held to contain more than is strictly warrantable in relation to the influence exerted over the ovum in the womb subsequently to fertilisation; for sex and build, it may be affirmed, are the inevitable sequences of the subtle and indefinable attributes inseparable from germ and sperm cell, and which no changes subsequent to conception can affect. But acceptance of this does not materially weaken the argument that the condition of the mother will react with the most positive effects on the being which derives the material for its growth from her; whether this shall be towards strength or weakness must absolutely depend on the quality of the nutriment that is afforded. And Sir Benjamin Richardson goes on to say, "Perfect build or deformity is at stake, a man, a woman, or a monster of either sex. Now is the time, when mental serenities or mental perturbations of fear, anger, jealousy tell through the mother on what she is bearing for the future." This is a view which may well excite the profoundest concern; nor is it one that can be at once discarded as of no significance on the ground that mental characteristics, if not merely physical ones, are direct products of inheritance, and are unalterable by any external influence. The facts of heredity, as they have been perhaps too confidently called in the past, face us with less hardy assurance than was natural to them when their claims to acceptance were less open to dispute; and in the uncertainty of the present there is an abounding reason to give at least a tentative acceptance to theories which, when substantiated by research, must be fraught with such great consequences to humanity. But it is the stimulus to thought and the incitement to prevention which thought affords that is chiefly valuable in such teachings as this; and, indeed, all the essays contained in the *Asclepiad* offer this best kind of help to those who are earnestly endeavouring to assist the movement forward. In the number of the work referred to above there are several papers that are eminently suggestive and useful, and one especially, on "The Moment for Blood-letting," with which the volume commences, will be found of great practical value.

◆

UNLICENSED HOUSES FOR SINGLE LUNACY PATIENTS.

A CASE recently disposed of before the Bristol magistrates is of considerable importance, and worth the attention of the general medical profession. A lady residing at Portishead answered to five summonses taken out against her for unlawfully receiving and detaining alleged female lunatics in a private unlicensed house. This lady set up an establishment for boarders five years ago; later she received invalids, and latterly mental cases. One of these is described as suffering from delusions, such as that her food was poisoned. This led to refusal of food. Two others presented marked mental symptoms, and when by an order of the Lord Chancellor the place and its inmates were subjected to medical inspection certificates were granted accordingly, with a certain reservation in one case. The defendant pleaded guilty to certain of the charges, and a mitigated fine was imposed. This prosecution is personally interesting to the medical profession, because all medical men are liable to have cases of mental disease in private practice, and cases where, though mental symptoms are present, lunacy cannot be certified. In the case of one of the ladies whose names appeared in the public press in connection with this trial—a young lady—the presiding magistrate observed as follows:—"An allegation has been made that Miss ——— suffered from mental disease, and it is a very serious statement to make with regard to any person, and especially in the case of a young lady. No evidence has been produced that would lead to any conclusion that she is of unsound mind." It is deplorable that the young lady's name should have appeared at all, and it is a fresh sign of the foolishness of the English Act of 1890 that such publicity was necessary in the interests of justice. A magistrate in this case properly asked the prosecuting counsel to define "lunatic or alleged lunatic," but received little satisfaction beyond a reference to the interpretation clause. The clause defines a lunatic as "an idiot or a person of unsound mind," a definition that could be torn to ribbons by opposing counsel in a court of law. The Act is by no means explicit on the subject of single patients in private houses, and medical men must often be at a loss how to proceed in such cases. The prompt and early treatment of incipient mental disease is of the utmost importance; there are strong prejudices against asylum treatment until the opposition of the family is overcome, and then a temporising expedient, such as a boarding house, is sure to commend itself. It was frankly admitted by the prosecution in the Bristol case that there was not the slightest suggestion of any improper treatment of the inmates by the defendant. Why, then, the concealment? Was it ignorance of the law or a desire to save the fee exacted for licence? The latter is scarcely a consideration that could weigh in this case, for there is no suggestion of a parsimonious spirit in the allegations of the prosecutor. Undoubtedly there has been too much "care of the insane" exhibited in the framing of the Act. All that is really required to secure them against improper treatment could have been attained by much simpler means.

◆

Notes on Current Topics.

Inadequate Vaccination by Medical Men.

The Medical Officer of Health for Bristol (Dr. D. S. Davies), in his last report, complains of the growing practice adopted by certain medical men of vaccinating in one tiny spot. He points out that this practice affords by no means an adequate protection for any length of time against the disease, and if, as he says, vaccination is obtained and paid for there is at least a moral obligation that it should be done in what is recognised to be an efficient manner, especially as it may be obtained gratis at any vaccination station. Small-pox is too serious and too fatal a disease to be trifled with, and vaccination in one small place is mere trifling. The outcome of this expression of opinion was that the Clerk of the Sanitary Authority was instructed to inquire into the cases referred to by the Medical Officer of Health, and, if evidence could be obtained, to take proceedings. We quite agree with Dr. Davies in his strictures, but, of course, it should be borne in mind that medical men have a good deal of prejudice to contend with—for which those silly infatuists the anti-vaccinators are responsible—among poor persons as far as vacination is concerned. Despite this, however, medical men should be true to their profession, and insist upon performing vaccination properly, notwithstanding the objection of the friends.

Determined Suicides.

The hero of a novel, when he is down on his luck, very frequently determines to commit suicide with his fully-charged revolver. Almost as frequently, by a happy chance, when he pulls the trigger the first cartridge refuses to explode. He refrains from testing the weapon any further, thanks Heaven for his lucky escape, and he succeeds in everything he undertakes thereafter. Not so the man who committed suicide in Edinburgh a little time ago, and whose case was related by Dr. Herbert Littlejohn at last week's meeting of the Edinburgh Medico-Chirurgical Society. Using a revolver of American make, he had to pull the trigger four times before the weapon went off, three unexploded but indented cartridges being found afterwards in it and one discharged case. The bullet had traversed the brain from side to side from an aperture in one temporal bone to within an inch of the calvarium on the other side. Fractures of both tables of the skull radiated from the bullet wound in several different directions. Dr. Littlejohn also showed the skull of and the hatchet used by another suicide in an almost more determined case. A servant girl had not long recovered from influenza, and may perhaps have had some love troubles. Left alone in her mistress's house one day, she went to the bath-room, drank an ounce of laudanum, hit at her skull with the hatchet ten to a dozen times, and fell into the bath which she had previously filled with water, and in which she was found drowned. Examination showed that there were nearly a dozen parallel and linear cuts through the scalp over the upper frontal region with a similar number of lines on the skull, each of which had broken the outer table of the bone. The other organs presented the usual symptoms found in cases of opium-poisoning and drowning. The extraordinary part of the second case is that the girl gave no previous evidences of mental derangement or of a disgust of life, save some slight taciturnity.

Boycotting Extraordinary.

Prejudice dies hard, says the proverb, and this saying is exemplified in the persistency with which our contemporary the *Lancet* continues to boycott the now flourishing British Gynæcological Society. Not only does our contemporary boycott the proceedings, but not even the announcements of coming meetings are admitted to the diary for the week. Well might the President protest against such an unexampled and arbitrary proceeding. The British Gynæcological Society can no longer be classed among the neo-societies. After the usual vicissitudes it has been placed on a firm footing, and as to the value of the work done at the meetings, there is no room for hostile criticism. Surely the time has come when the foolish prejudice once rampant against the study of the diseases of women *per se* should be allowed to die out. The question is one more of persons than of principle, but it seems absurd that a journal which professes to represent in a more or less perfunctory way professional opinion should deliberately and with malice aforethought do its best to crush out of existence a popular and useful society. We plead not so much on behalf of this particular society as against a policy in journalism which, if allowed to pass unchallenged, bids fair to reproduce all the most obnoxious features of an obsolete depotism. The Society, for the matter of that, has gone its way uninjured by this unjustifiable persecution, for such it amounts to, but in the interests of medical journalism it is to be hoped our contemporary will desist from a line of conduct which has absolutely nothing to recommend it.

Death by the Electric Current.

The recent fatality at the Blackfriars Station of the London Electric Supply Corporation, by which one worker lost his life, and another had a narrow escape, brings into appropriate notice the statement of M. D'Arsonval, the distinguished French scientist, that, in his opinion, electricity kills no one, but produces a state of anæsthesia with complete unconsciousness and apparent suspension of vital functions, which condition is scarcely distinguishable from death. M. D'Arsonval writes with special reference to the "electrocution" of criminals in America, and he declares that, if artificial respiration were produced when death was apparent, the patient would in most cases recover. He goes on to say that, in the case of these electrocuted patients, it is the post-mortem examination which kills, and not the carrying out of the sentence of the law. Without accepting M. D'Arsonval's opinion implicitly, we quote it as a suggestion to hospital surgeons to try artificial respiration to the fullest extent in any such case before they conclude that the patient is actually dead. In estimating the risks of electric lighting it ought to be remembered that the Electric Supply Corporation differs from all companies as to the extremely high tension at which it works its dynamos. It sends its current from Deptford to London at a tension of 10,000 volts, whereas the average tension at which the current is distributed by other companies does not exceed 2,000 volts. By employing this extreme tension the Company is able to send its current for considerable distances without using heavy and expensive conductors, and without losing much of the current in transmission. But, on the other hand, it suffers from having to deal with a current which is liable to break out of the cable wherever the slightest fault is to be found, just as water bursts out if it is at high pressure, a fault which otherwise would be unimportant. When the high tension current reaches London it is necessary to break it up and to reduce it to the tension suitable for domestic consumption, and this it does by passing it through "converters" set up at local stations. It was in the shifting of the current from one set of converters to the other that this accident happened.

Hydrophobia Again!

Apropos of the remarks which we made last week on this subject, we note that five persons have been recently bitten in Liverpool, and that "the dog was destroyed, and after examination by Dr. ——, was pronounced to have been suffering from rabies.' Accordingly, the whole five were forthwith transmitted to Paris for Pasteurism, and no doubt they will appear in the returns as victims saved from hydrophobia. But, we may ask, where is the evidence that the dog was rabid—and where the proof that, supposing him to be so, any virus was communicated to the persons bitten? First, the initial stupidity is committed of killing the dog before ascertaining whether it was really mad. Next, we are asked to believe that it was mad because Dr. —— examined it and thought so. But not even Pasteur himself can pronounce upon the existence of rabies in the dog by any post-mortem appearances, still less by a superficial exterior examination, which is usually considered conclusive in these cases. He expresses no such opinion until he has actually tested the matter by inoculating rabbits with the dog virus. Under these considerations, we, for the sake of argument, submit that the dog in this case was not mad, that if it were it is very unlikely that it communicated the rabid virus to the persons bitten, and that the examination by a medical practitioner in no respect serves to confirm the existence of rabies. Our purpose in making these observations is certainly not to discourage precaution; we wish to discredit the utterly stupid procedure of killing the dog (which effectually prevents the existence of rabies being proved or disproved), and the equally idiotic proceeding of muzzling all the dogs in a county because a stupid policeman considers one of them to be mad.

Efficacy of Vaccination.

Salford has recently had, unfortunately, an opportunity of studying the efficacy of vaccination, inasmuch as the town has suffered from a severe epidemic of small-pox, and the Medical Officer of Health, Dr. Paget, has published some striking figures. Several facts are notable:—1. That amongst the vaccinated under 20 years of age there was no death. 2. That the mortality amongst the vaccinated, at all ages, was only 6·8 against 34·3 amongst the unvaccinated, and 16·7 amongst those whose vaccination was doubtful. It seems to be proved by this experience that the protective efficacy of vaccination wears off, to some extent, after twenty years of life, and that, to retain protection, the process ought to be repeated. As to its efficacy on the whole, the evidence is conclusive to any one except an anti-vaccinator.

Antiseptic Surgery at Guy's Hospital.

SINCE Lister first taught surgeons how to treat their operation wounds, it may be said, in some respects, that the antiseptic treatment of wounds has tended rather to elaborateness than to simplicity. But in the gradual development of this process it has always been Lister's aim to avoid any unnecessary detail and to reduce his method to a system as devoid as possible of complicated procedures. It is of interest to note that, despite the numerous antiseptics now in use, Sir Joseph Lister still shows his preference for carbolic acid. A solution of one in twenty of this drug serves for cleansing everything in connection with the operation, such as the hands, the instruments, the wound, &c., and the dressing employed is the double cyanide gauze, soaked in the same or a weaker solution. The perchloride of mercury is now quite out of favour with Sir Joseph. Apropos of this subject mention may be made of the progressive measures now being adopted at Guy's Hospital for securing thorough asepticism. We learn from our contemporary the *Guy's Hospital Gazette* that everyone engaged in an operation, except the anæsthetist, in the well of the hospital theatre, is required to wear a white closely-buttoned macintosh, stretching from the neck to the heels, having short arms; over the macintosh and arms is worn a brown holland coat wrung out in one-twenty carbolic. Up to the present this innovation has had the effect of causing a good deal of curiosity in the school, and the theatre is consequently greatly crowded during the operations, for the purpose of seeing the white-robed gentlemen in their new apparel. In following out antiseptic surgery to its legitimate end the fact, of course, should be remembered that it is quite easy to overstep the mark, and to introduce into Listerism elaborate procedures which seem to be the outcome more of superstition than anything else. Superstition is apt to take the place of common sense when the surgeon, in his extreme anxiety to exclude germs from his operation wounds, allows himself to be haunted by the ubiquitous microbes. The logical reasoning, it appears to us, deducible from the practice of highly elaborate antiseptic precautions is that, if superstition be once permitted to have sway, antiseptic surgeons will feel it to be their duty to operate under glass cases.

The Indecent Advertisements Act.

WE are glad to learn that something is about to be done to strengthen the Indecent Advertisements Act. It is well known that the Act only applies to advertisers who issue circulars in the public street, while those who choose to insert advertisements in any public print which will accept the announcements can publish anything they please, however scandalously subversive to the public morals. The worst offenders who play into the hands of this large and unscrupulous *genus* are the weekly papers catering mostly for the masses, and some of the so-called religious papers. A high legal authority has pointed out that, as the Indecent Advertisements Act cannot be made to apply to advertisements inserted in newspapers, he is prepared to bring in a short Bill remedying the Act in this respect during the course of the next session. The sooner that the amendment becomes law the better. Only a week or two ago no less than *three columns and a half* of quack advertisements, couched in the most barefaced filthiness, appeared in one of these papers. Each advertisement was an invitation to pregnant women to apply for medicines concocted for the purpose of interrupting the natural course of pregnancy. From the lavish extent with which these advertisers "boom" their wares, it is evident that their trade is a most prosperous one, and that of all quacks they are reaping the best harvest. Many of them describe themselves as "Doctors," and doubtless by this assumption of title still further add to their ill-gotten gains.

An Interview with a Medical Centenarian.

THE medical centenarian Bossy, of Havre, is still in the active pursuit of his profession. He has recently given some details of his life and habits to an interviewer, which show that his energy and spirit for a man of his age are remarkable. "I am," he says, "an enemy of all *régimes*; I have adopted none especially. My formula is this: Use everything, abuse nothing. Every morning, winter and summer, I am out of bed at seven o'clock; I shave myself because I have no time to attend at the barber's. For some considerable period I have abandoned driving about in my carriage, owing to the fatigue it causes me. I always visit my patients on foot; the other day, for example, I began my visits at eight in the morning and was engaged until noon. My appetite is excellent, and I have not lost a single tooth. So far as illnesses are concerned, personally I have never had any. There is only one thing wanting in me, and that is one eye. This is how I lost it: Four years ago the left eye became slightly inflamed. I put myself under the care of a colleague, who treated me with leeches, to which I strongly objected. Eight days later I was blind in the eye, and subsequently the organ was removed." The absence of precise details respecting the conditions present which led to the loss of the eye renders comment on the case impossible. Meanwhile the vigorous vitality still displayed by Dr. Bossy after his long innings of life is nothing less than marvellous. His must be an extremely interesting personality.

A Case of Idiopathic Tetanus.

AN inquest has recently been held in Longford on the body of a girl who had died of tetanus in the Infirmary. There seems to have been no very special point about the case except the conduct of a local practitioner, who is said to have attended behind the back of the dispensary doctor, Dr. Maguire. This practitioner seems to have conceived the idea that the girl was suffering, not from tetanus, but from hysteria, and that she could be cured by a vigorous shaking up, which, it appears from the evidence, that he then and there administered. It was sworn that he "lifted the deceased's head off the pillow by the hair," and afterwards dragged her by the hand outside the door on her bare feet with nothing on her but a cloak. This treatment of the poor creature seems to have been adopted in defiance of the opinion of the Dispensary Medical Officer, Dr. Maguire, and his consultant, both of whom declared the case to be one of tetanus, which it afterwards proved to be. Upon the facts disclosed in the report of the inquest we feel bound to say that, if the evidence given was truthful, the conduct of the practitioner referred to was extraordinary, and, as it afterwards appeared, destructive of the chance of the poor girl's recovery. The case is an illustration of the unwisdom of charity patients calling in outsiders to revise the well-considered opinions of doctor and consultant in cases of this sort. There are probably facts and motives behind the screen respecting which the inquest report gives us no information.

The Dermatological Society of London.

From time to time we have been asked to afford information about the self-styled Dermatological Society of London. The information afforded by the "Medical Directory" and kindred publications is extremely meagre, but from private inquiry we have ascertained that the society consists of some thirty members, more or less self-elected, and that these thirty gentlemen, having taken to themselves the well-sounding title of the "Dermatological Society of London," protected themselves against unwelcome intruders by decreeing that thirty should be the outside limit of membership, and applicants for membership are consequently dismissed with the formula that there is no vacancy. Now a certain proportion of the gentlemen connected with this "close corporation" are not known to the profession at large as having any particular right to pose as dermatologists, hence they occupy places which ought in common fairness to be left free for others whose dermatological attainments are of public repute. The proposal to reform the society on a more democratic basis has all along met with a determined opposition from the *clique* who rule the roost, and who desire to maintain their position of "the only recognised dermatologists." The only alternative was to start another society, admission to which would take place in accordance with the regulations which custom has sanctioned in respect of the older societies. For a number of gentlemen, however eminent, to form themselves into a close body, and to arrogate to themselves a metropolitan title is an unmitigated piece of impertinence which we are glad to find has excited universal reprobation. Indeed, we learn that the movement for the creation of a new society has had the desired effect of startling these gentlemen out of their composure, and they have, under pressure, condescended to assist in organising the new society. Now that publicity has been directed to their conduct they may be sure that any departure from the normal rules in respect of membership will be sharply criticised. It is not for the committee to decide whether or not an applicant is a specialist. Every practitioner of good repute, whether specialist or general practitioner, ought to be eligible, and unless this is conceded the creation of another dermatological society will still have to be thought of. The study of diseases of the skin is quite wide enough to justify a society devoted to its pursuit, the more so as "skin cases" fail to receive anything like adequate attention when brought before the general societies, medical or surgical.

Sewer-Gas laid on to Private Houses.

Sanitary authorities, in their zeal for the hygienic welfare of other people, are at times apt to overlook the beam that is in their own eye. They are inclined to become lax in administration, especially as any attempt at rigorous work not only irritates householders, but also entails an increased expenditure upon the ratepayers. Seldom, however, have the sins of a Corporation been more emphatically thrown in their faces than in the case of a late report of the Health Committee of Dublin. In speaking of the connection of houses with main drains, Alderman Macguire remarked, "It might be said that we in laying cross drains from sewers to houses are really laying in sewer-gas to them, as the gas company lays in gas, and, undoubtedly, that is exactly what we do, so that unless the householder is specially careful to provide an interceptor trap to stop the entrance of sewer-air, he will have a dangerous connection, which may cost him his life and the life of his children and servants." The Dublin Corporation evidently believes in plain speaking. It would be well if many other Corporations took a leaf out of the same book, at any rate, so far as health matters are concerned.

The Sad Death of a Medical Man.

Blood-poisoning is now one of the rarest of complications of operation wounds with which surgeons are called upon to deal—thanks to the beneficial results of antiseptic surgery. Still it is the case that the active and virulent pathogenic germs never lose the opportunity of propagating all the evil of which they are capable whenever the circumstances are favourable. For this reason, therefere, medical men cannot be too much on the alert to prevent inoculating themselves or others upon all occasions in which professional services are being rendered to patients suffering from septic wounds. Sometimes the contributory causes to any such inoculation may be of the simple description, as, for example, in the case of a medical man named Dr. Robert Clark, who has just died from acute septicæmia at Lancaster. We learn that he happened to touch a small excoriation upon his nose before washing his hands after dressing a sloughing bed-sore from which one of his patients was suffering. As the result of this inadvertent inoculation blood-poisoning rapidly developed, and death took place from septic pneumonia within a week of the untoward accident.

A week since we referred to a duel in Austria in which a medical man was shot dead. A similar tragedy has now to be recorded as having occurred in Berlin. Dr. Roever, the deceased, fought a military equipment manufacturer with pistols. No less than eight shots were exchanged, and at the last round the doctor fell dead.

A Pastrycook and his Sponge Cakes.

It is no doubt a merciful dispensation of Providence that the average citizen does not see the places in which his food is kept and prepared; otherwise his appetite would be liable to many a shock by reason of this or that unpleasant association. The ways of bakers in their underground bakehouses, where foul air, sewage, and filth of various kinds struggle for the ascendancy, have been so often and so forcibly exposed that the dish is now regarded as somewhat stale by newspaper readers. Nevertheless, little real reform in this much-needed direction appears to have been as yet accomplished. Not long since a well-known and energetic London medical officer of health discovered that several underground bakehouses in his district were flooded by a reflux of sewage in certain flooded conditions of the Thames. At one of these places he found sewage-soaked flour which the owner admitted he intended to make into pastry. It is to be hoped that cooking would to some extent, if not altogether, rob these nameless horrors of their power for evil in the human body. No such purifying influence, however, would apply to the hands of workmen, to baskets, trays, and other contaminated surroundings. The movement of bakehouse inspection owes its resuscitation chiefly to the energy of the Medical Officer of Southwark. Considerable activity has also been shown in Marylebone. In the last-named district a baker was fined £4 for having a preparation of unsound eggs in his possession which were unfit for the food of man. The defendant admitted that he was about to use in the making of Bath buns and sponge cakes eggs which "stank," to use the emphatic description of the sanitary inspector. The whole question of the preparation of our food supplies requires systematic and thorough overhauling.

Exhumation.

The extreme step of exhuming a body is, as a rule, entertained by the Home Secretary only in cases where there is sufficient evidence to warrant the gravest suspicion as to the cause of death. It has never been hitherto undertaken, we believe, in order to satisfy friends as to the correctness of diagnosis and treatment by the medical man who attended deceased. Yet that extraordinary object seems to have actuated a Mr. Petre, of Margaretting, near Chelmsford, who actually succeeded in getting an exhumation order for a coroner's jury to inquire into the cause of death of his infant child. The father was dissatisfied with the treatment deceassd received from Dr. Smith, of Ingatestone, and his solicitor stated that his only motive was to definitely ascertain the cause of death. The jury formed their opinion upon the medical evidence only, and returned a verdict that death was due to natural causes, and that Dr. Smith was warranted in his treatment. Mr. Petre, through his solicitor, expressed himself as perfectly satisfied with the result of the inquiry. He is said to be a cousin of Lord Petre, which may to some extent explain the fact that he was able to obtain an exhumation order. Certainly any ordinary citizen in doubt as to the skill of his medical man under similar circumstances might as well hope for Parliament to take up his fancied grievance as for the Home Secretary to grant an exhumation order.

Factory Work and Infant Mortality.

The rate of infant mortality, as a sum total, is determined by many contributory causes. In manufacturing districts it is greatly influenced by the employment of young mothers in the factories. The reasons for this are sufficiently obvious, and the truth of the main proposition can hardly be called in question by anyone who has studied the returns of infant mortality in any of our great industrial centres. This subject was brought forward prominently at the Berlin Conference, and since then a clause was introduced into the Factory Act of 1891 which forbids the employment of mothers within a month of child-birth. Dr. Tatham considers a month is not a sufficiently long period, and that it should be extended so that the mother could rear the child. His suggestion may be sound in theory, but it would certainly rouse very great opposition among the married women who are wage-earners in factories. The disabilities of the sex are already considerable, and this proposed addition would lend itself to easy attack.

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Public Inquiry into Sudden Deaths in Scotland.—Some time ago we intimated that there was a desire on the part of some in Scotland for the adoption of a system of coroners' inquests similar to that which holds in England, and that bodies of working men had petitioned the powers in office to institute such courts or at least a public inquiry. We, at the time, pointed out that the change would be retrograde, the office of coroner in Scotland having fallen into desuetude during the last century, cumbrous and costly. We are glad to see that Mr. Thomas Trotter, advocate, in an address to the Leith Liberal Club, is of the same opinion. His arguments against the new proposal are:—1. It is costly. 2. It is cumbrous. Jurors require to be cited, and a large number of other legal formalities have to be gone through, and this in every case of sudden death, be it suicide, heart disease, or apoplexy. Cases like the latter are more suited for a private post-mortem examination by a medical man than for a public inquiry. 3. Publicity often opens a door for the guilty to escape. In conclusion Mr. Trotter thinks that the present system might be improved if the autopsies were made by expert medical jurists.

We are inclined to think that the working men only desire another form of inquiry in the hopes that they may obtain some more benefit from the Employers' Liability Bill by having a soft-hearted jury, probably recruited from their own class, to adjudicate in the first place with regard to accidents, instead of an impartial fiscal.

Accidental Poisoning at the Edinburgh Fever Hospital.—The Law Committee of the Edinburgh Town Council one day last week voted £125 to the mother of a maid-servant lately in their employment at the City Hospital in satisfaction for her claim of damages for her daughter's death. It appears that her death must be added to the long roll of those caused by the accidental administration of carbolic acid. Suffering from indigestion, she was ordered "a dose of salts." The contents of a bottle labelled poison and standing where it should not have been were given inadvertently, and the girl died shortly after. We referred to this case in our last issue.

The Edinburgh Infirmary Managers.—The matter *re* the staff as Managers has been remitted to the Law Committee. The two members of the staff appointed by the College of Surgeons to the Board have had their staff appointments made interim by the Board until the matter is settled. The Committee of Contributors have expressed strong disapproval of the appointment of any of the staff as Managers. The two members in question are still obstinately resolved to persevere in their course.

A Hospital Scandal.—During the past week the town of Airdrie has been thrown into a state of excitement in consequence of some extraordinary revelations which have been made regarding the management of the Fever Hospital and the treatment of the patients. The feeling is all the more acute as many discharged patients have from time to time expressed themselves as to the bad management and treatment now openly complained of, and although some little notice may have been taken, yet the matter was always hushed up. Now, however, the matter has come to a crisis, and the matron was arrested and brought before the Sheriff and committed to prison, and the assistant matron has been dismissed as well as all the nurses, the vacancies being filled with new ones. It is stated that all fevers were placed indiscriminately in the same ward. The more serious charge against the matron is that, during the month of October last, she assaulted the now deceased John Colye, then a patient in the hospital, suffering from typhoid fever, and that while he was in a state of delirium she struck him and tied him down in bed with a rope for seven hours on two occasions, on account of which treatment his friends attribute his death. She is further charged with ill-treating another male patient in a similar manner, threatening to put him in the dead-house, and third, that she assaulted Annie Graham, a fever patient, aged 8 years, by striking her with a scrubbing-brush and otherwise maltreating her. It may be added that on Saturday last the matron was liberated on bail.

The New Professor of Midwifery in Glasgow University.—The friends of Dr. Murdoch Cameron purpose giving him a complimentary dinner at an early date in order to celebrate his appointment to the Chair of Midwifery in the University. Postcards are being sent out widely in order to ascertain the number of those who will avail themselves of the opportunity. It is stated that the price of the ticket will probably be about 5s.

Vaccination Prosecution.—A Mr. Walter Currie was again brought up, charged for the third time with refusing to have his child vaccinated (the same child). His lordship said he would make the penalty the very lowest he could. He was not authorised under the statute clearly by the law to give an admonition, otherwise he would. The penalty was fixed at one shilling, with two guineas of expenses which had been occasioned by some technical objections. The alternative would be twelve hours' imprisonment.

◆

MEDICAL SOCIETY OF LONDON.

Last Monday's meeting, January 22nd, was a clinical evening.

Mr. Gould showed a piece of rubber tubing 11 inches long which a draper's assistant had accidentally introduced into his bladder. He made out its situation by means of the cystoscope and then managed to remove it without too much difficulty.

Mr. Swinford Edwards and Mr. Hurry Fenwick referred to cases in which the cystoscope had proved useful in localising foreign bodies in the bladder prior to removal. In Mr. Fenwick's case the foreign body was a portion of wax taper which, floating on the water, was exceptionally difficult to seize with the lithotrite. This, however, he managed to effect after a good deal of trouble.

Mr Ballance showed two men upon whom he had performed wiring of the patella for fracture. The results were good, especially in one case. He had performed this operation some six or seven times for fractured patella, and always with a satisfactory result, although he never used a drainage tube. He made the incision laterally in order not to leave a cicatrix over the front of the joint. He pointed out that in very few cases of fractured patella could the fragments be brought together unless the fractured bone was exposed, on account of portions of the aponeurosis and clots falling between the fragments. He always performed every step of the operation himself, dispensing with any assistance, in order to reduce the risk of infection. Passive movements were begun in ten days, and the patients were up and about in a month.

Mr. Turner pointed out that the operation was essentially *the* operation for recent cases of fractured patella. He suggested that the use of wire for sutures presented certain disadvantages, but he knew of no other substance that had the requisite strength.

Mr. Watson Cheyne said that union would probably be obtained whatever substance was used to suture the fragments, but if wire were used then the patients could be allowed to move about before bony union had taken place, which was a distinct advantage. He had never seen a case of transverse fracture of the patella in which the fragments could possibly have been brought together by any operation short of laying open the joint.

Mr. Bruce Clarke thought that six weeks' rest was desirable before commencing movements.

Mr. Bidwell said he had recently had occasion to lay open the joint in a man in whom a previous fracture of the patella had been wired by the subcutaneous plan. He found that no union had ever taken place, the fragments being kept in position only by means of the wire. He pared the edges and wired them securely together with a perfectly satisfactory result.

Mr. Bruce Clarke showed a man who had been circumcised seven months before on whose penis a horn, an inch or two in length, had formed since that time.

Mr. Sheild suggested that this outgrowth was probably due to the accidental implantation of some epithelial cells at the time of operation, and he pointed out that similar growths sometimes followed ulceration of sebaceous cysts and molluscum contagiosum, and were also met with on the fingers from the ingrafting of cells driven in by pins or needles.

Dr. Morgan Dockrell showed several cases, and others were shown by Mr. Hurry Fenwick, Mr. Turner, and Dr. Pasteur.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE DISINFECTION OF WOUNDS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—For the purpose of demonstrating the superiority of solutions of the biniodide of mercury over the bichloride in the treatment of poisoned wounds, the following experiments were performed on mice at the Bacteriological Laboratory, King's College, London, with the usual License.

December 7th.—Three mice inoculated with virulent anthrax gelatine culture, on wounds near the tail a quarter of an inch in diameter. One mouse was used as a "control." The second was irrigated with a 1 in 1000 solution in potassium iodide, after waiting five minutes; and the third similarly, after waiting half an hour. The irrigation was repeated at intervals of a quarter of an hour, for an hour and a half, when both mice were left with the control, in separate boxes, for the night, the wounds being left exposed.

8th.—All three mice living. Irrigation commenced again at 9.30 a.m. and continued at intervals until 5 p.m. when the process was again discontinued for the night, the wounds being left open.

9th.—"Control" and first mouse found dead at 9.30 a.m. The exact time of death of each not known. The third mouse was alive and well. Anthrax bacilli found in the blood and spleen of both dead mice.

10th.—Third mouse alive and well. Lotion applied once only during the day. Wound healthy.

11th.—Mouse alive and well. Lotion applied at intervals until the evening, and then entirely discontinued.

13th.—Mouse alive and well.

December 13th.—Second experiment. Three mice inoculated in the same way, and one used as a "control." After waiting a quarter of an hour, the wounds were bathed with a 1 in 500 solution of biniodide. This was peated every quarter of an hour, for an hour and a half. he wounds were then left bare for the night.

14th.—All three mice living at 9.30 a.m. Lotion applied intervals until 4.30 p.m., when the "control" and one the others were seen to be feverish, with rapid breathing d feeble motor power.

15th.—One mouse and the "control" found dead; the cond alive and well; lotion discontinued after 2 p.m.

16th.—Mouse alive and well; wound healthy.

17th and 19th.—The same healthy condition observed.

On December 19th a third experiment was done with ur mice and one "control." Inoculation as before with latine cultures of anthrax at 11 a.m. Irrigation with 1 1,000 solution of the biniodide in iodide of sodium, mmenced at 11.30 a.m. and repeated every quarter of an our for five and a half hours, when all the mice were left r the night, their wounds being left bare.

20th.—Irrigation begun again at 10.30 a.m., and connued until 5 p.m. The "control" died at 12.30 p.m. wenty-five hours after inoculation).

21st.—Lotion applied as usual. One mouse found dead t 10 a.m.; another died at 11.15, forty-eight hours after oculation, and twenty-three hours after the death of the 'control."

22nd.—The two remaining mice alive and well.

25th.—Mice alive and well, wounds dry and healthy.

Remarks.—To unprejudiced minds the above experiments were not needed to prove the superiority of the iniodide over the bichloride, because the fact has been onclusively demonstrated in bacteriological experiments y Drs. Miquel and Rueff; in chemico-pathological xperiments by Dr. Woodhead; and clinically by Dr. Luff, nyself, and many others during the last seven or eight years. The bichloride precipitates albumen, and the binodide does not; hence the former is retained in the tissues, whilst the latter is eliminated. The brilliant results ttainable by the bichloride are not denied, but the dangers are so great from the deposition of the albuminate of mercury that Hoffman of Vienna, Tarnier of Paris, and many others have at length denounced it. The persistent advocacy therefore of this drug by leading British surgeons and obstetricians in spite of the proved expediency, from every point of view, of the addition of iodide of potassium, is inexplicable except on the ground of prejudice.

The Editor of the *British Medical Journal*, by refusing to publish replies to Dr. Robert Boxall's letter of November 25th, 1893, and Dr. Clement Godson's of November 18th, has deliberately fostered this prejudice; and in dealing with the question, has shown himself destitute of the first principles of editorial impartiality. The practice of thus allowing an editor to give away a discussion in any direction which his "supreme judgment" dictates, in the way regularly adopted and continually and most dishonourably practised by Mr. Ernest Hart, is, I contend, deserving of the severest censure by the Association.

Dr. Boxall is so eager to condemn the biniodide that he accuses me of "calling the kettle black" before I have even mentioned the drug. He goes far into the regions of fancy, to find a danger in "Iodism," from the use of a 1 in 1,000 or 2,000 solution *to a wound!* Truly objections are hard to invent; especially when it is remembered that the only treatment for mercurialism is full doses of potassium iodide. Dr. Boxall's antagonism is especially peculiar when one reads in his recent address to his students that he "looks forward to the day when some equally efficient but satisfactory"—safe (?)—"antiseptic will be found to take its place." The addition of the iodide of potassium to the corrosive lotion is all that is required to furnish all that Dr. Boxall desires; but unreasoning and deeply-rooted prejudice evidently prevents him adopting so simple a method; for it is impossible that all the facts which have so frequently been published in the medical journals regarding the safety and value of biniodide solutions have escaped his notice.

There are now, however, no loopholes for such objectors to the use of the biniodide for all septic processes and poisoned wounds.

Anthrax poison can be destroyed by the drug in open wounds, when all other antiseptics, as shown by Schimmelbush and reported in your columns in May last, fail to check its progress. Surgeons and obstetricians must therefore use it to the exclusion of all other antiseptics if they intend to secure perfect freedom from danger with the brilliant results of the bichloride.

I am, Sir, yours, &c.,
C. R. Illingworth,

"UNQUALIFIED MEDICAL MISSIONARIES."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is to be hoped that, as the straightforward Medical Press and Circular has called attention to the "Zenana Medical College" and its actions, the Medical Council will at once call before it those medical practitioners who are conducting examinations and granting medical diplomas in connection with it. Lately, a pamphlet, termed "White Fields," bearing upon the above diploma-granting college, has been sent me. I notice that the following medical practitioners form the "Medical Board of Examiners":—"Dr. William Ord, St. Thomas's Hospital, medicine; Mr. Pickering Pick, St. George's Hospital, surgery; Dr. Dakin, midwifery, and diseases of women and children."

The "Medical Referees are "Dr. F. T. Roberts and Dr. Gilbart Smith," while the "Hon. Sec." is Dr. G. de G. Griffith. Among "the Patrons" are Sir Wm. Muir, K.C.S.I.; Sir W. MacCormac, F.R.C.S.; Surgeon-General Sir W. G. Hunter, M.D.; Professor Macnamara, ex-President R.C S.I.; Dr. Walter Smith, Vice-President R.C.P.I.; while on "the Committee" are Dr. Griffith, Dr. Kapadia, Chororg Muthu, Esq., M.D.; and H. T. Sylvester, Esq, M.D., V.C.

In the balance sheet, opposite "Students' Payments," the sum of £146 9s. 9d. is placed; and £12 12s. for "coaching fees." On p. 28, the following occurs:—"Our Society grants a *Diploma*, signed by the Board of Examiners, after successful examinations at the end of two years curriculum." Now, I have asked the Hon. Sec. and several of the "Medical Board of Examiners" for a cancelled diploma form, yet I have been steadily refused this. Why? Will the "Medical Board" supply a copy of the diploma form for publication in the Medical Press? If not, why not? I have also asked for a curriculum of study. Will this also be supplied to you, if not to me? If not, why not. It would be well if this college ceased to grant diplomas. What is the good of having regular colleges for women, at which they must study for five years, if other colleges with a two years' course of study, are established. I see it stated, in the above "White Fields" that if medical women are "filled with the Holy Ghost and common sense," they can do untold good. But even supposing the properly registered women practitioners are not so "filled"—a point which I would dispute—can they not do *more* good? Dr. C. H. F. Routh's apology for the Zenana "Medical" College is a very poor affair indeed, and if he has stated all that can be said in favour of his pet, then his case is as weak as is his statement, that the great majority of medical practitioners have adopted the practice of medicine "as a *vocation.*" But even if it is a "vocation," does he mean to assert that we practitioners have not as clean hands and as pure hearts as those who are supposed to be "filled" with some superior influence? If a "two years' curriculum" turns out a better practitioner—even for niggers—then why does the General Medical Council insist on a five years' course? Which is right? I would ask Dr. Routh to publish the diploma form as granted by his "College," also the curriculum of study, and to cease trying to show that the aim of the Medical Council in establishing a preliminary examination, a five years' course of study, and the passing of rigid examinations is a meaningless farce. Why does he range his operation along with that of the "natives" of "India, Africa, China, and Burmah," whom he says "care very little for qualified persons." On what authority does he make this startling statement? Where is his *proof?*

In the "Syllabus of Lectures" I notice the following:—"Anatomy, dermatology, dental surgery, surgery, clinical diseases, materia medica, pharmacology, and case-taking, midwifery, medicine, ophthalmic surgery, tropical diseases physiology," are mentioned. Also, Mr. T. Cooke, F.R.C.S., gives instruction in practical anatomy at £1 1s. for each demonstration, while practical dispensing is taught at the Hospital for Women, 32 Lupus Street. "All students who go up for their *Final Examination* previously pass that of the Obstetrical Society and obtain the *Midwifery Diploma*."

Now, Sir, if the above points do not show the necessity of the Medical Council to interfere with the action of the medical practitioners connected with the above Zenana "College," then the sooner the Medical Council withdraws its recommendations relative to medical education the better, and so be guided by the very intelligent "native" opinion referred to by Dr. Routh.

I am, Sir, yours, &c.,

Liverpool. **Robert R. Rentoul.**

◆

Literary Notes and Gossip.

A chemist named Bartolomeo, of Milan, has claimed the prize of 50,000 francs offered by the Paris Academy for a cure of diphtheria which he professes to have discovered.

⁂

The Austrian journals are congratulating themselves on the literary ability of their professors, and point to the success of Gruber's work in England and America as proof of their undoubted merit.

⁂

A lady interested in Medical Missions has offered two scholarships, of the value of £100 and £50 respectively, to women who desire to educate themselves for medical work in the mission field. These scholarships are tenable at the Edinburgh School of Medicine for Women, and we are asked to announce that particulars can be obtained from the Secretary of that School, Surgeons Square, Edinburgh.

⁂

"Research Prizes," each of the value of fifty guineas, are offered in our advertisement columns to-day by the Royal College of Physicians of Edinburgh for the two best Essays on Medical Subjects by Fellows, Members, or Licentiates of the College. Competitors are permitted to choose their subjects and the Council will award the prizes.

⁂

The past year will not rank as a distinguished one for its literature. So far as medical works are concerned, 1893 was singularly deficient both in number and ambition. There was a faint rush of works on biology and hygiene; of the former little need be said, as they were hurried forward to meet the new examination requirements. The literature of hygiene was, however, greatly enriched by the production of Stevenson and Murphy's book. Morris's new work on "Anatomy," and Sir Wm. Jenner's "Fevers" may also be mentioned as features; whilst McEwen's "Diseases of the Brain," Stair's "Brain Surgery," and Goodall's "Microscopical Examination of the Human Brain" may be referred to as evidences of the direction of modern innvestigation. The remainder of the 93 new books of the year differed little from the ordinary run, some of these will doubtless reach, in due course, to new editions, but the majority will be lost in the abyss of "blighted hopes," to which so many thousands have been previously consigned.

⁂

But if the year has been barren of important new books, it has produced its full share of new editions of standard authors. Of these we may mention a fourth edition of Field's "Diseases of the Skin," Whitelegge's "Hygiene and Public Health," "Vertebrate Embryology," by the late Prof. Milnes Marshall; Powell's "Diseases of the Lungs and Pleura," Ireland's "Blot on the Brain," Gray's "Anatomy," Harrison's "Urinary Organs," Waller's "Physiology," and a revised edition of the late Dr. Fleetwood Churchill's "Obstetric Nursing," by Dr. T. More Madden.

Of important books by foreign authors, there have been some notable translations into English, paramount among which are Sir Wm. Dalby's edition of Professor Politzer's "Text-book on Ear Diseases," Fuch's "Text-book of Ophthalmology," Strumpfel's "Text-book of Medicine," Metchinkoff's "Comparative Pathology," Weismann's "Germ-Plasm."

⁂

The December number of our Paris contemporary, *Revue Bleue*, contains the first of a series of essays on " Professions en Angleterre," by M. Max Leclerc, and inaugural paper deals with "doctors." The author, our experience, is almost the first foreigner who has s ceeded in getting a lucid and correct idea of our carri lum and our chaotic system of degree and licence-givi The medical profession, says M. Leclerc, has obtained autonomy, but not its patent of nobility, and the rea he gives for this deprecatory statement is that the prof sion in Great Britain requires to be "raised and rende more select" (s'épurer) its present condition being t absence of sufficiently drastic and sufficiently reliable te of the standard of general edncation exacted of can dates.

⁂

We are not in a position to controvert the authe assertion that "the medical profession, as it exists England, comprises the humblest duties of an ill-remu rated, lightly-esteemed, manual occupation—as well as t highest flights of speculative science." M. Leclerc ref to the Society of Apothecaries, and "a certain Scot corporation" as issuing diplomas the value of which likens to that of the degree of M.D. formerly accord to all-comers by the notorious University of Jena. T author next discusses in a very spirited way the n superannuated apprenticeship system, and follows step step the efforts (?) of the General Medical Council to rai the standard of the preliminary examination—efforts wh have not, so far, had any very practical result. M. Leck may be congratulated on the accuracy and perspicacity his observations, which bear the stamp of personal researc but we doubt whether his revelations will tend to incre the respect of his fellow-countrymen for our medical i stitutions.

⁂

An attractive little publication, "The Practical Coo Book," has just been issued by the Liebig Extrac Meat Company, Limited. Out of the one hundred a eighty receipts which it contains the following des special mention :—Asparagus soup, oxtail soup, mu pilau, jugged hare, shepherd's pie, dressed veget marrow, Parmesan omelette, caper sauce, savoury cus and jellies. These and all the other receipts plainly il trate the many different uses to which the Compa Extract can be put in the preparation of toothsome di The book, which is published at 1s., can be had with cost by members of the medical profession on writin the Secretary of the Company at 9 Fenchurch Ave London, E.C.

⁂

The last half-yearly volume of "Braithwaite's Re spect," July—December, 1893, is now before us, and i only superfluous praise to say that the high standar excellence attained by previous issues is well mainta in the present volume. As a record of contempo medical literature the "Retrospect" stands in an u valled position, and no medical practitioner anxious to k pace with the progress of his profession should omi consult its pages. With the "Retrospect" by his side a v to a medical library for reference purposes would scar be needful, for it is only true to say that the "Retrosp forms a library in itself.

⁂

In blossoming into the *Quarterly Medical Journal*, *Sheffield Medical Journal* now appeals to a much wi circle of readers, and the promoters are to be congr lated upon their enterprise. The January number of excellent journal commences with an important art "Some Forms of Diarrhœa, especially Morning Diarrh from the pen of Dr. Lauder Brunton. A more instruc contribution upon this subject has, in our opinion, n before appeared. Moreover, a most useful diet tab appended, which is applicable to the cases with which article deals. Nine other original communications contained in the number, all of which may be per with profit. Abstracts and summaries and other it complete the number, which thus makes an excellent s in the present year.

New Books and New Editions.—The following have been received for review since the publication of our last monthly list:—The Microscopical Examination of the Human Brain, by Edwin Goodall, M.D. Lond., B.Sc. The Student's Dictionary of Medicine, by Alex. Duane, M.D. Infectious Diseases Notification and Prevention, by Louis C. Parkes, M.D. Lond. Common Neuroses (2nd ed.), by J. F. Goodhart, M.D., F.R.C.P. Modern Gynæcology, by Chas. H. Bushong, M.D. Advanced Physiology, by John Thornton, M.D. Text-book of Normal Histology, including the Development of the Tissues, by Geo. A. Piersol, M.D. An Introduction to Midwifery, by Archibald Donald, M.D. Ed., M.R.C.P. Headache and other Morbid Cephalic Sensations, by Harry Campbell, M.D. Lond. A Practical Handbook of Midwifery, by F. W. N. Haultain, M.D. Index Catalogue of the Library of the Surgeon-General's Office, Washington, vol. xiv. Blue Book on the Health of the Navy for 1892. The Art of Living in Australia, by P. E. Muskett. The Healing of Rodent Cancer, by Inglis Parsons, M.D., M.P. The Latin Grammar of Pharmacy, sixth edition, by Joseph Ince, F.C.S., F.I.C. Dictionary of the Active Principles of Plants, Alkaloids, Bitter Principles and Glucosides, by Chas. E. Sohn, F.I.C., F.C.S.

◆

Medical News.

The French Hospital.

The 26th Annual Dinner of the French Hospital and Dispensary is announced to take place on Saturday, Feb. 3rd, at the Whitehall Rooms, under the presidency of H. E. M. Decrais, the French Ambassador, supported by the Lord Mayor and the Sheriffs of the City of London, &c.

The Parke Memorial Fund.

A meeting of the General Committee will be held at the Shelbourne Hotel, at 4.30 p.m. on Friday next, the 26th inst., to receive the report of the Executive Committee, and to decide upon the application of the Fund and the form the proposed memorial should take.

Harveian Society of London.

The annual meeting of the Harveian Society was held on Thursday, January 18th. The retiring President, Mr. Malcom Morris, delivered an address, and the following office-bearers were elected:—President: Dr. Eastes. Vice-Presidents: Mr. Drew, Dr. Maguire, Mr. Rayley Owen, Mr. D'Arcy Power. Treasurer: Mr. Cripps Lawrence. Hon. Secretaries: Dr. Boxall, Mr. Peyton Beale. Council: Dr. Gomer Davies, Mr. Henry Davis, Mr. Dodsworth, Dr. Evans, Dr. Charles Gross, Dr. William Hill, Mr. Howard Marsh, Mr. Malcolm Morris, Mr. Roughton, Mr. Morton Smale, Dr. J. Edward Squire, and Dr. A K. Willis. The annual *conversazione* of the Harveian Society, held subsequently, proved very successful, and was well attended. Nearly 200 members and visitors were present. To the retiring President, Mr. Malcolm Morris, is due the initiation of an interesting and instructive exhibition of the various methods of depicting disease The efforts of the President were ably seconded by the Honorary Secretaries, Mr. E. W. Roughton and Dr. Robert Boxall, in bringing together examples of chromo-lithography, electrotyping, and engraving, engraving on wood and stone, drawing, painting, photography, and microphotography, wax-modelling, plaster-casting, &c. During the course of the evening a selection of instrumental music was given by the Prince's Band. The room was specially upholstered for the occasion by Messrs. Spillman and Co.

British Gynæcological Society.

At the Annual Meeting on Thursday, Jan. 11th, the following office-bearers were elected for the ensuing year: Honorary President: R. Barnes, M.D., F.R.C.P. President: T. Savage, M.D., M.R.C.P., F.R.C.S. (Birmingham). Vice-Presidents: Dr. Apostoli (Paris), A. H. Freeland Barbour, M.D., F.R.C.P.E. (Edinburgh), Fancourt Barnes, M.D., F.R.S.Ed. (London), F. C. Batchelor, M.D. (Dunedin), Vincent Dickinson, M.D. (London), W. H. Fenton, M.A., M.D. (London), James Murphy, M.D. (Sunderland), H. A. Reeves, F.R.C.S.E. (London), Heywood Smith, M.D., M R.C.P. (London), J. W. Taylor, F.R.C.S. (Birmingham), Professor W. J. Smyly, M.D. (Dublin), W. Gill Wylie, M.D. (New York). Treasurer: J. A. Mansell Moullin, M.B., M.R.C.P. (London). Librarian: George Granville Bantock, M.D., F.R.C.S.E. (London). Council: C. H. Bennett, M.D. (London), Professor J. W. Byers, M.D. (Belfast), G. Gleghorn, M.D. (New Zealand), T. M. Dolan, M.D. (Halifax), C. Godson, M.D., F.R.C.S.Ed, M.R C.P. (London), W. C. Grigg, M.D., M.R.C.P. (London), T. B. Grimsdale, M.B. (Liverpool), R. H. Hodgson, M.R.C.S. (London), F. Bowreman Jessett, F.R.C.S. (London), L. Jones, M.D. (London), J. Macpherson Lawrie, M.D. (Weymouth), E. Holland, M.D. (London), J. A. Shaw Mackenzie, M.B. (London), H. W. Maunsell, M.D. (London), H. Michie, M.B. (Nottingham), J. R. Morison, F.R.C.S. (Newcastle), Professor T. Oliver, M.D., F.R.C.P. (Newcastle), F. A. Purcell, M.D. (London), A. W. Mayo Robson, F.R.C.S. (Leeds), Professor A. R. Simpson, M.D., F.R.S.Ed. (Edinburgh), Professor Japp Sinclair, M.D., M.R.C.P. (Manchester), W. Travers, M.D., F.R.C.S. (London), A. Wallace, M.D. (London), S. Sunderland, M.D. (London). Editor of Journal: Leith Napier, M.D., F.R.S.Ed. Honorary Secretaries: Leith Napier, M.D. (London), F. F. Schacht, M.D. (London).

The first annual dinner of this Society, which, is, however, by no means a recent arrival in the scientific world, took place on Thursday last, January 18th, at the Holborn Restaurant, the retiring President, Mr. Bowreman Jessett, in the chair. He was supported by a very representative number of guests and friends, thus testifying to the fact that the prejudice always felt against newly-formed societies is at last giving way to more friendly feelings on the part of those who belong to the older bodies. Among those present may be mentioned the Master of the Apothecaries' Society, Dr. Hare, Mr. Lawson Tait, &c., together of course with the president-elect, Dr. Savage. In responding to the toast for the Society the President, after reviewing the growth of gynæcology as a separate speciality, alluded in outspoken terms to the unheard-of form of boycotting from which the Society had suffered (and in respect of one contemporary still continues to suffer) at the hands of certain organs of the medical press. He referred to the fact that the editor of the particular organ referred to not only declines persistently to publish reports of the proceedings, but even refuses to insert the announcements of the meetings. He gracefully acknowledged the readiness with which we of the Medical Press have given the publicity of our columns to reports of the proceedings, and congratulated the Fellows on the fact that the boycott had at last been overcome in respect of the other contemporary. A judicious selection of musical performances afforded an agreeable variation of the post-prandial *menu*, and altogether a very agreeable evening was spent.

Lessons of the Pilgrimage to Mecca.

The number of Mohammedans, says a correspondent in a morning contemporary, who annually make the pilgrimage to Mecca is steadily increasing, and it is difficult to see how cholera is to be kept out of Europe while the pilgrims are allowed to embark on homeward-bound steamers when suffering from the disease. If a quarantine camp were established in the desert between Mecca and Jeddah, and pilgrims were not allowed to embark for their homes until they were passed as "clean," the difficulty would to a great extent be surmounted; but neither the Turks nor the Arabs are likely to take the initiative, and unless England (who is largely interested from the number of her Indian Mohammedan subjects) takes some decisive action in the matter, things will go from bad to worse.

Society for the Relief of Widows and Orphans of Medical Men.

At the last meeting of the Court of Directors of this Society, Sir James Paget, President, in the chair, it was resolved to distribute a sum of £1,226 among the 55 widows, 9 orphans, and 4 orphans on the Copeland Fund, now in receipt of grants. A fresh application for assistance was read, and a grant made. The expenses of the quarter were £75 19s. 6d. Two new members were elected, and the deaths of 5 reported. A sum of £791 had been received from the trustees of the late John Robinson Peile, Esq. The Directors determined to call a special general meeting and to recommend that a grant of £50 should be made at it to the daughter of a deceased member. After Lady Day next the offices of the Society will be at 11, Chandos Street, Cavendish Square, London.

Dr. Tibbits, as was anticipated, has been nonsuited in his action for libel against the *Charity Record*; in fact, the jury declined further evidence when the case was half through.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of The Medical Press and Circular, may now be had at either office of this Journal, price, 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Original Articles or **Letters** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

Bathybius.—The subject was one which was discussed by Professor Huxley some years ago. In this particular, therefore, our correspondent is perfectly correct.

Medical Student.—In the new volume of the Medical Directory our correspondent will find all the information which he requires. All the special hospitals are included in the list.

Dr. Mortimer Granville.—We hope to have space for your communication in our next.

Mr. Jessett's "Evolution of Gynæcology" is unavoidably held over.

Enquirer.—We will endeavour to ascertain what has become of the funds, and by whom distributed.

A NEW ADULTERANT.

The newest discovery in the way of adulteration of milk has been exposed by the Public Analyst for the St. Saviour's (London) Board of Works, who has detected starch water as an admixture. From the milkman's point of view it has the advantage that it not only makes the milk taste thick and rich, but it renders the detection of the added water more difficult for the analyst.

Dr. Martin's letter came to hand as we were at press. We hope to find space for it in our next.

Dr. Philip Lee.—The report is unavoidably held over to our next

"WHAT IS IN A WORD."

It was decided last week by the London Queen's Bench Division that a prosecution for adulterating rum could not be maintained because the analyst in giving his certicate of the adulteration used the words, "I estimate the sample to contain" so much water. The Court held that the word "estimate" is not a specific declaration of the fact, and that the analyst should have said "I find."

So Strange.—"You say that I was born in Berlin, papa? Well, then, where was mamma born?"
"In Magdeburg."
"And where were you born, papa?"
"In Hanover, my child."
"Isn't it strange that we three should have got to know each other?"—*Medical Brief.*

Meetings of Societies, Lectures, &c.

Wednesday, January 24th.

Hunterian Society.—At 8.30 p.m., Clinical Evening. The President: Cardiac Disease, with Traumatic Aneurysm of the Foot.—Dr. Bertrand Dawson: Aneurysm of the Innominate Artery.—Dr. Hingston Fox: Graves' Disease in a Boy aged twelve years.—Dr. Cotman: Carcinoma of the Breast.—Mr. Campbell McDonnell: Tabes Dorsalis without Locomotor Symptoms.—Dr. Arnold Chaplin: Bronchiectasis. Dr. Arthur Davies and Dr. Fred. J. Smith will also show cases. Dr. Rayner D. Batten will exhibit a New Clinical Pulse Manometer.

West London Hospital.—At 5 p.m., Dr. Donald Hood: The Symptoms of Acute Pneumonia. (Post-Graduate Course).

Thursday, January 25th.

Neurological Society of London (20 Hanover Sq., W.).—At 8.30 p.m., Annual Meeting. Presidential Address by Prof. Ferrier: Recent Work on the Cerebellum.

Ophthalmological Society of the United Kingdom.—At 8.30 p.m. Living and Card Specimens at 8 p.m.:—Dr. Ernest Clarke: Pulsating Exophthalmos in a Child.—Dr. E. C. Kingdon: Symmetricial Changes at the Macula Lutea in an Infant. Papers: Mr. Jonathan Hutchinson: School Ophthalmia.—Mr. Hill Griffith: Cases of Orbital Tumours.

Friday, January 26th.

Clinical Society of London.—Living Specimens at 8 p.m.:—Mr. Eve: Modified Excision of Elbow.—Mr. Pearce Gould: A Case of Thoracoplasty.—Dr. Francis Hawkins: Displacement of the Heart in a Child, due to Fibroid Phthisis.—Dr. Sidney Phillips: Rheumatic Nodules in an Adult.—Mr. Turner and Dr. Penrose: A peculiar form of Muscular Atrophy.—Dr. Sansom: A Case of Aphasia.—Dr. Mott: (1) Bulbar Paralysis after Thrombotic Necrosis; (2) Paraplegia following Typhoid Fever. Papers at 9 p.m.:—Mr. H. H. Clutton: Three cases of Endosteal Sarcoma of Radius.—Mr. John D. Malcolm: Nephrectomy for Malignant Tumour in a Patient under Two years of age.—Mr. Arbuthnot Lane: (1) Acute General Suppurative Peritonitis secondary to Appendicitis, Removal of Appendix, Recovery; (2) Multiple Epitheliomatous Growths developing in Psoriasis treated with Arsenic more than Thirty years.

London Post-Graduate Course.—Hospital for Consumption, Brompton, 4 p.m., Dr. P. Kidd: Cases of Cardiac Disease.

Saturday, January 27th.

London Post-Graduate Course.—Bethlem Hospital.—At 11 a.m., Dr. P. Smith: Acute Mania.

Monday, January 29th.

Medical Society of London.—At 8.30 p.m., First Lettsomian Lecture, by Mr. F. Treves, F.R.C.S.: "Peritonitis."

St. John's Hospital for Skin Diseases.—At 6 p.m., Dr. Morgan Dockrell: On the Erythemata.

Vacancies.

Darlington Hospital and Dispensary.—House Surgeon (unmarried). Salary £100 per annum, with board and lodging. Applications and testimonials to the Hon. Secs. on or before Jan. 27th.

Parish of Lambeth.—Assistant Medical Officer and Dispenser. Salary £125 per annum, with board, apartments, and washing. Applications and testimonials to the Clerk on or before Jan. 30th.

Royal South London Dispensary.—Surgeon-in-Ordinary. Honorarium £20 per annum. Applications and testimonials to the Committee of Management on or before Jan. 31st.

Westminster Hospital Medical School.—Lecturer on Bacteriology. Applications to the Dean on or before Feb. 6th.

Appointments

Benson, J. H., M.B., F.R.C.P., L.R.C.S. Irel., Consulting Physician to the City of Dublin Hospital.

Brick, M., L.R.C.P., L.M., L.R.C.S. Irel., *pro tem.*, Medical Officer of the Tralee Dispensary District.

Leach, J., M.A., M.B., C.M. Aberd., House Surgeon to the Southern Hospital for Women and Children, Manchester.

Mason, W., L.R.C.P., L.M., L.R.C.S. Edin., *pro tem.*, Medical Officer for the St. Austell Workhouse.

Modlin, J. Gibson, M.B., B.S. Dunelm, L.S.A. Lond., Medical Officer for the Monkwearmouth District of the Sunderland Union.

Preston, J. R., M.R.C.S. Eng., L.R.C.P. Lond., House Surgeon to the Jessop Hospital for Women, Sheffield.

Read, Marvn, M.D. Camb., D.P.H., M.R.C.S., Honorary Physician to the Worcester Infirmary.

Traquair, J. H., M.B., C.M. Edin., Junior Assistant Medical Officer to the Staffordshire County Asylum, Burntwood.

Wallis, F. C., M.B. Cantab., F.R.C.S., Surgeon to the Orthopædic Department at Charing Cross Hospital.

Births.

Smith.—Jan. 10th, at 52 Camden Square, London, N.W., the wife of J. Burnett Smith, M.B., of a daughter.

Marriages.

Anderson—Cobbold.—Jan. 16th, at the Pro-Cathedral, Kensington, Charles Macdonell Anderson, M.B., C.M. Ed., M.R.C.S.E. and L.R.C.P. Lond., to Maud Chevallier, elder daughter of H. Chevallier Cobbold, Esq., of Kensington.

Bate—Dutton.—Jan. 1[illegible]th, at St. Cuthbert's, Kensington, George Bate, M.R.C.S.E., L.S.A. (late R.N.), to Mary Anne (Annie), third daughter of the late Dr. James Dutton, of London, W.

Deaths.

Haliday.—Jan. 16th, Edward Halliday, M.D., at his residence, 2[illegible] Sandford Road, Ranelagh, co. Dublin.

Miller.—Jan. 16th, at 58 Bedford Gardens, Kensington, Robert Miller, M.D., aged 87.

Myers.—Jan. 10th, at 2 Manchester Square, W., Arthur T. Myers, M.D., F.R.C.P., aged 42.

Paine.—Jan. 15th, at his residence, Elmsfield, Cardiff, Henry James Paine, M.D., in his 78th year.

Reid.—Jan 11th, at Brussels, Thomas Bassett Reid, Brigade-Surgeon English Army (retired).

Scougal.—Jan 14th, Edward Fowler Scougal, M.A. Aberd., M.D., C.M. Edin., of Marsh Wood Road, Huddersfield, Yorkshire, aged 38.

Shaw.—Jan. 13th, at Colney Hatch Asylum, Hugh Grosvenor Shaw, M.R.C.S., one of the Resident Surgeons at the Asylum, aged 32.

Thursfield.—Jan. 16th, at 342 Uxbridge Road, Thomas Greville Thursfield, M.D., aged 52.

Wagstaff.—Jan. 16th, at Leighton Buzzard, Philip Wynter Wagstaff, M.R.C.S., L.S.A., aged 83.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

Original Communications.

SCHOOL OPHTHALMIA. (a)

By JONATHAN HUTCHINSON, F.R.S., LL.D., F.R.C.S.,

Late President of the Royal College of Surgeons, England; Consulting Surgeon to the London Hospital.

IN view of the occurrence of several outbreaks of a form of ophthalmia, leading to granular lids chiefly, but though not exclusively, in schools I think a useful purpose will be served by bringing the subject forward, especially as before many months have passed many of us may be called upon to advise school committees in reference thereto. In years past I have on several occasions had to report on epidemics of this form of ophthalmia in workhouse schools, but not until quite recently have I heard of it in middle class schools. During the last few months its existence in five well managed schools in distant parts of the country has come to my knowledge. The type of the disease seems to be mild, and the first stage, that of congestion, is specially liable to be overlooked on account of its very slightly marked character. A number of cases indeed have escaped recognition until the lids were distinctly granular, and even the patient himself could not recall more than a day or two of irritability. At one school which I visited at least 50 per cent. of the boys and some of the teachers had suffered. The type was very similar in all the cases. There had been a few days irritability and redness of the eyes, which passed off almost without treatment to be followed by a definite but mild condition of granular lids. Most of the eyes which I inspected showed only the papillary conditions but a few had small sago grains. None of them showed advanced or severe conditions, but many had resisted more or less prolonged treatment. Several boys having returned after the vacation uncured, the disease rapidly spread. No fault could be found with the sanitary condition of the school. I was informed that in several instances the disease had spread to other members of the family to which boys suffering from the disease had returned. These I cannot vouch for, but I know of other cases in which no contagion occurred, but these were cases in which the treatment was being carried out and due precautions observed as to towels, &c. In this particular school 5 per cent. of the boys were recognised to be suffering from the disease in September, 1893, rising to 40 per cent. in October, and to not less than 50 per cent. in December, in spite of boracic acid lotions and strict lavatory precautions, in fact every precaution with the exception of isolation. In no case, however, had the upper lid been everted for treatment. Many families in the town suffered, but they were chiefly those which had been visited by children from the school.

The disease is the same in the rich as in the poor, as is proved by the fact that the terms used in a report written by me in 1866 in respect of a workhouse school might very well serve in respect of this particular high class school. The chief difference was that in the workhouse the disease had been unrecognised for six years, while in the school it had been recognised within six months. At Brentwood (a school of 310 children) I found about a third suffering from ophthalmia of a chronic catarrhal form. In only a few had it passed into a badly granular form, and I did not consider that any of the lads presented the true trachoma bodies. The chief difference in the high school cases was that a granular condition of the lids was more easily assumed, and with much less of preceding conjunctivitis. This, however, may be merely due to a difference in my powers of observation, and to my recognising as slightly granular, conditions which I should formerly have classed as healthy. This leads me to remark that the diagnosis of slightly granular lids is by no means easy. After all, the papillæ which, when enlarged, constitute the "sandy lid" are normal structures, and large allowance must be made for varying conditions within the limits of health. In the doubtful cases no amount of experience will enable anyone to say with certainty, that such granulation is morbid. The only safe plan during the prevalence of an epidemic is to treat all suspicious cases as if real. If there is a difficulty in diagnosis before, it is infinitely greater after treatment.

The disease to which we used to apply the term catarrhal ophthalmia (at Moorfields) was an acute conjuctivitis attended by great congestion and mucous secretion. The ocular conjunctiva was always affected, and the congestion had the peculiarity of being in patches, the vessels being so closely placed as to simulate ecchymoses. Both eyes were affected, and with almost equal severity. There was never any pain or intolerance of light. It seemed invariably to occur in groups, several members of the family suffering at the same time, but on the other hand it did not spread in epidemic form nor were more than a few families affected at a time. This may possibly be explained by the fact that the disease is of brief duration, and, while it lasts, is so conspicuous as to keep the patient at home and warn others off. The attacks lasted usually from a week to ten days, and though recovery was hastened by astringents it seemed capable of spontaneous cure. It is not liable to recur, and, as a rule, leaves no sequelæ. In short, it is a malady which, although really trivial, looks alarming. The particular form of ophthalmia under discussion is quite distinct from the suffused eye associated with coryza. Moreover, it spread in families by contagion and without any other symptom of "cold." The name which would most definitely attract attention to its leading feature would be "Family Ophthalmia."

This form of conjunctivitis does not lead to granular lids, though it may conceivably do so in persons predisposed thereto by race or state of health. I cannot reject a suspicion, however, that these cases of so-called catarrhal ophthalmia are only very exaggerated forms of that which is the parent of granular lids. Against this suppostition is the fact that in considerable epidemics not a single patient has ever exhibited any condition approaching it. There are a number of reasons for believing that the contagion does not travel through the air, nor do I think that defective ventilation and the like have any appreciable influence in spreading the disease, except so far as they favour direct infection. The possibilities of actual contact in schools are too great for it ever to be practicable to exclude them, and there is absolutely no evidence that the disease can prevail as an epidemic in a town or community amongst individuals who are not brought into personal communication with each other.

(a) Abstract of paper read at the Ophthalmological Society, Thursday Jan. 25th, 1894.

Good reasons can be alleged for believing that the cause of granular lids is a special, or if I may venture to call it so, a specific, affection. Sporadic cases of granular lids are rare, and they almost invariably occur in epidemics or in those who have suffered in school. The few isolated cases I have seen have been in persons of Celtic or Hebrew descent.

Experience of this form of ophthalmia among soldiers favours the idea of its specificity. It is indispensable that we should banish the idea that purulent ophthalmia in soldiers implies any connection with contagion from gonorrhœal discharges. The ophthalmia which prevailed in the army in Egypt, and has since proved such a scourge in the armies of Prussia, Holland, and elsewhere, was no other than a severe type of that which in our workhouse schools leads to granular lids. We must bear in mind, moreover, that neither the purulent ophthalmia of infants nor that of adults results in granulations.

The practice of sending home soldiers suffering from granular lids is responsible for the spread of the disease in homes and villages, and it is high time that attention should be drawn to a most reprehensible line of conduct, since it is very possible that to it, in respect of workhouses and other schools, we owe the increased prevalence of the disease which appears to threaten us.

Our experience of military ophthalmia justifies the belief that it owns no predisposing conditions, attacking indiscriminately those who become exposed to the contagion. Such alleged predisposing conditions as small close rooms, overcrowding, and the like are obviously precisely those likely to favour direct contagion.

One of the most difficult problems connected with the subject is to determine when and under what conditions the victims of granular lid ophthalmia may mix with others and abandon systematic treatment. In the English race the disease but rarely becomes a source of danger to sight, and the medical officers of our workhouse schools have not as yet taken any special cognisance of the great risk involved. Not only have children suffering from ophthalmia been admitted into the schools, but those only half cured have been allowed to leave without remonstrance. It may be difficult to prevent this, but some attempt should be made Hospital schools should be provided into which chronic cases can be received, and where they can remain until they get well. At a certain large public school every year brings forty or fifty cases of ophthalmia in spite of isolation and proper treatment. This is probably the result of contagion from boys incompletely cured being prematurely permitted to re-enter the classes.

Rumours have reached me of the existence of ophthalmia at a number of middle class schools throughout the country, and I cannot help suspecting that a skilled inspector of the middle class schools might reveal a far wider prevalence of the malady than we at present recognise. In some instances I suspect that the school authorities have concealed its existence, and in others have simply neglected it.

The first report on ophthalmia in workhouse schools was by the late Sir William Bowman in 1858, followed by another by Mr. Haynes Walton in 1861. My own report was in 1866. Although, with others, I thought the ophthalmia one that could easily be cured, I am proud of the fact that I then asserted that contagion and contagion only was its cause, and recommended then, as I do now, isolation as the only means of preventing its spread. None of the measures adopted have proved sufficient, and our workhouse schools still suffer to a most lamentable extent from ophthalmia, and the state of things calls loudly for further effort.

The disease undoubtedly underwent a great increase during the period that isolation was wholly neglected, and its present prevalence is just in proportion to the neglect of this measure. Unless proper precautions are promptly taken workhouse ophthalmia will shortly become an appanage of our middle class schools just as it has long been of those for paupers. From schools it will spread to private families, and unless something in our race peculiarities protects us, bad cases of trachoma may become as common with us as they have long been in France and in Ireland. No one who has attended the practice of a Paris ophthalmic clinic and seen what Mr. Critchett calls the noble army of martyrs standing in a row and waiting in turn to have their eyelids brushed can fail to appreciate the urgent necessity for doing all that is possible to prevent the development of such a state of things. We must not presume too much upon racial advantages, for the facts to which I have alluded disclose a very serious danger.

With regard to preventive measures all cases of inflamed eyes occurring in schools should be promptly isolated and all large schools should be provided with apartments ready for the emergency. In the majority of cases doubtless a cure might be quickly effected, but a careful examination of the lids should be made before the pupil is allowed to associate with others, and should be repeated a few weeks later whether there are any symptoms or not.

Any suspicion of granular lids should lead to immediate isolation and to special attention being paid to local and constitutional treatment. It is probable that the liability to lapse into a chronic state, to pass from the papillary into the sago-grain state, depends very much upon the vigour of the patient and in such a state tonics and fresh air become of great importance. The place of residence should be dry and bracing.

In the event of an epidemic in a school ought the establishment for a time be broken up and the pupils sent home? Certainly not. The disease has nothing to do with the location of the school or with the buildings. It is due to contagion only. If parents insist upon having their children home it must be on their own responsibility, and with a full knowledge of the risk of the disease spreading in their own families. Apart from the danger which such a course entails of spreading the disease broadcast, by retaining the children at the school under one surgeon we make more sure of their having skilled treatment efficiently carried out.

When the disease has not progressed beyond the papillary stage isolation for a month or two will probably suffice, but if true trachoma bodies are present then the period of isolation may extend to months or even years. If the condition has become chronic and resists treatment the child ought probably to be regarded as unfit ever to mix with healthy children Such children should be sent to invalid schools at the sea side or in other bracing situations. It is worth while adopting any measures, however, expensive or troublesome in order to ensure their cure.

I do not wish to be considered an alarmist, but as a cause of blindness on the Continent the ophthalmia of granular lids stands second only to the ophthalmia of infants. Our duty is first to be well informed ourselves, and then to inform the public. The profession generally and not only ophthalmologists must learn to appreciate the importance of the problem before us.

◆

At one time the authorities in India were convinced that Europeans could not live in that country without alcoholic stimulants, and consequently the formation of temperance societies were actually prohibited among the soldiers. No such prohibition, however, now exists, and the English soldiers in India to-day include no fever than 20,000 total abstainers.

HOMŒOPATHIC CLAIMS TO DISCOVERIES OF REMEDIES.

By MORTIMER GRANVILLE, M.D.

Attention has been called to an omission on my part in a short paper on "The Treatment of Influenza," (Med. Press, Dec. 13th, 1893) which I regret because it may seem to evince some discourtesy to members of the profession professing "Homœopathy." I would not be thought guilty of that crime against common sense which is unhappily approved by the majority of our so-called "leaders," namely, the treatment of Homœopaths, as outside the pale of professional sympathy. I differ from those who hold that heretical view of therapy, perhaps even more widely than many of the vehemently orthodox gentlemen who condemn homœopathy without having the smallest notion what it really is they are knocking their dull heads against. There is plenty of room in the world for the pursuit of different chimeras, and the ignorant worshippers of "soda" and "potassa" can surely keep aloof from the infatuated believers in infinitesimal doses without quarrelling.

Commenting on my paper, a correspondent, Dr. J. H. Clarke (Med. Press, Dec. 20th), says I appear to have learned something of Hahneman. I am glad to say that forty years ago I picked up a great many pieces of valuable information from the Father of Homœopathy and some of his personal pupils, but the virtues of camphor was not one of them, for the simple reason that two hundred years ago, and no doubt a great deal earlier, it was perfectly well known that the "resine blanche," as it used to be called, was possessed of certain properties which were thus described :—

"Il est hysterique, il appaise les vapeurs, il resiste au venin, il aide à la respiration, il reveille les esprits, on s'en fert exterieurement and interieurement ; on en fait sentir aux femmes histeriques, au leur en applique sur le nombril," and most significant of all, "on en peud au cou dans un noüet pour les fiévres intermittentes."

It did not need any effort of such genius as the disciples of Hahnemann claim for their master to conclude that a drug thus endowed would be useful in a depressing malady like influenza.

This controversy about Hahnemann's "discoveries of remedies" has raged for some years, notably when the homœopaths charged Dr. Lauder Brunton with purloining most of his information from the Prophet of their Faith.

In 1887 somebody alleged that "Dr. Brunton not only takes a large number of his drugs from the homœopathic materia medica, but he likewise takes his indications for the use of those drugs from homœopathic works. Where else could he derive his knowledge that pulsatilla is a remedy for acidity, diarrhœa, earache, and epididymitis ; that bryonia is useful in pleurisy, pneumonia, meningitis, peritonitis, and rheumatism ; that thuja is good for condylomata ; viola tricolor and rhus toxicodendron for eczema ; gold for ozæna, achillæa for uterine hæmorrhage ; ignatia for hysteria, melancholia, infantile convulsions, and nervousness ; and fifty other remedies and their indications strange to old physic ?" It is time that the preposterous claims to originality made by homœopaths in regard to what they are pleased to call their materia medica were exposed and refuted. As a matter of fact there are few, if any, drugs in the so-called homœopathic list of remedies which are not taken bodily from French or German works on drugs many of which are either out of print or forgotten. It would be as easy to show that the pretended discoveries of the homœopaths are in fact plagiarism as it is to demonstrate that *similia similibus curantur* is a fallacy in the logical sense of that word.

Every practical student of therapeutics is aware of the fact that all substances, whether fluid or solid, which have any action on the organism produce two apparently opposite and contradictory series of effects, resulting from their exhibition in difference doses, or, in some instances, observable in successive stages of their operation. Thus, to take a familiar example, opium acts as an excitant in one dose and as a sedative in another dose, the precise proportions required to produce the several effects varying with the individual, but the two phenomena being presentable in every case. Castor oil may stand for a drug which promotes peristaltic action in one part of its operation and checks it in another, not by producing exhaustion as is too commonly assumed but specifically, as was found by the experiments made with castor oil during the prevalence of cholera. Better illustrations of the fact to which I allude might be found, but these occur to me as familiar. Now it must be evident that if this be so *every* drug may be claimed as a "similar" by any one desirous of propounding the dogma *similia similibus curantur*, and ignorant or careless of the fact that all drugs have contradictory actions in different doses. The fallacy of the homœopathic system lies in this, namely, that the drugs employed by homœopaths are never given to cure disease in the doses which they allege will produce effects similar to the morbid phenomena they affect to regard as "indications."

In brief, the whole pretence is a juggle. Setting wholly aside the absurdity of infinitesimal doses, the very principle is a fallacy. It is, however, with the pretension to originality I wish now to deal. As Hahnemann first advocated his "Homœopathy" in 1796, it will suffice to show that the drugs which your correspondent accuses Dr. Brunton of having adopted from homœopathic works, and which he asserts to have been strange to old physic, were perfectly well known before that date. Not to go too far back, I will quote from that well-known work "Traité Universel des Drogues Simples," par Nicolas Lembert, published in Paris, 1698 :—

1. *Pulsatilla.*—"Elle est détersive, resolutive, propre pour la gratelle, pour inciser, pour attenuer les humeurs."

2. *Bryonia.*—"Elles purgent les serositez par le ventre et par les urines ; elles levent les obstructions, elles excitent les mois aux femmes, elles poussent l'arrièrefaix aprés l'accouchement : elles sont propres pour l'asthme."

3. *Thuja.*—"Ses feuilles sont resolutives, desiccatives, carminatives, sudorifiques. Son bois est detersif, cephalique, sudorifique, propre pour resister au venin, pour les maladies des yeux et des oreilles."

4. *Viola.*—"Elles sont pectorales, cordiales, adoucissantes, un peu laxatives, les feuilles, de violette sont émollientes, humectantes resolutives. La semence de violette est purgative, hydragogue."

5. *Rhus.*—"Ils sont fort astringents, propres pour la dysenterie, pour les flux de menstrues et d'hæmorrhoïdes, pour arrêter les gonorrhées."

6. *Achillea.*—"Elles sout détersives, vulneraires, astringentes, desiccatives, propres pour arrêter les cours de ventre, les hemorragies : on s'en fert exterieurement and interieurement."

7. *Igratia.*—This, according to evidence adduced by Alston in his "Materia Medica," published mdcclxx came into the Dutch shops about the latter end of the seventeenth century Alston makes the following quotation : "Viru habet roborantem et stomachicam ; conducit optime ad febres prœcipue intermittentes, in quibus datur media hora circiter ante paroxysmum ad ℈ss ; laudatur etiam ad pleuritidem spuriam, vertigineur, epilepsiam, passionem iliacam et diarrhœam."—Nucl, Belg., 112.

As to "Gold for ozæna" I have not thought it worth while to say anything seeing that in face of the multitudinous virtues with which this metal has been and still is credited it is open to anyone to to say it is a cure for anything. As to the "fifty other remedies" to which allusion is made, I cannot deal with these until they are named, but I venture to predict that in so far as they are genuine elements of the materia medica they will not be "strange to old physic" and will have been rediscovered not by Dr. Lauder Brunton but by the homœopaths! It may be objected that I have not proved that the drugs specified were specially used for the cure or relief of the maladies for which homœopaths employ them, or known to produce the effects with which Dr. Lauder Brunton credits them. This objection, I believe, can only be raised by homœopaths, because the properties assigned to each drug by the author cited above are obviously those which, if they did not directly suggest their use in certain stages of the diseases named, would explain their *modus operandi* to any ordinary therapeutist.

THE EVOLUTION OF GYNÆCOLOGY AS A SPECIALTY. (a)

By FRED. BOWREMAN JESSETT, F.R.C.S.,

President of the British Gynæcological Society.

It may not be out of place on such an occasion as this to give a short history of the origin of this Society and of the reason why it was thought to be not only desirable but absolutely necessary for such a Society as the British Gynæcological Society to be established.

To do this I think it will be well to give you a brief outline of the growth of gynæcology during the present century, and for this purpose I will carry you back to the year 1823. When that great man, Dr. Blundell, a man who lived half a century before his time, read a paper before the Medical and Chirurgical Society based upon experiments he had made upon animals, and from observations of the tolerance of the abdomen in man when wounded by accident or design, he concluded that moderate openings might be made in the human peritoneum which would not necessarily or even generally prove fatal from inflammation or otherwise, and further, that certain viscus or parts of viscus could be removed with comparative safety. He proposed that the Fallopian tubes might be divided, the ovaries removed, ovarian cysts extirpated, cancerous uterus excised, and in rupture of the bladder into the peritoneum that the abdomen should be opened and the peritoneum washed out. This paper was thought so little of by the Society before whom it was read that it was not deemed worthy of a place in the Transactions, and the doctrines propounded were looked upon as being wild and extravagant by his reviewers. I do not find any record of his having put his theories into practice.

After this the art of gynæcology seems to have slumbered until the year 1834 when the first speculum was introduced in London from Paris. This instrument for some years was looked upon with horror by many of the physicians and surgeons of the day. This was followed some twenty years after by the introduction of the uterine sound. It was not, however, until the year 1843 that the study of diseases peculiar to women was really made the subject of special attention, it was in that year that a hospital for women was established at Alabama in America by the late Dr. Marion Sims, and in the same year in this country the Soho Hospital for Women was established through the instrumentality of Protheroe Smith, followed in 1847 by the Samaritan Hospital, and later, the New Hospital and the Chelsea Hospital. It was asked what was the use of these special hospitals? The answer is that at the general hospitals at the time, and indeed, in some of the general hospitals now, gynæcology is in the unenviable position of being between two stools, as the late Dr. Aveling remarked, try the physicians and surgeons, and between the two it often fell to the ground.

It cannot be disputed that the art of gynæcology has advanced so fast that it must become a special study. Now, what have the special hospitals done? In the first place they have been the means of forcing upon the general hospitals the fact that gynæcology had been to a very great extent neglected. Further, through the position taken in the earlier days by the late Tyler Smith at St. Mary's, and Dr. Robert Barnes at St. George's Hospital, the gynæcologist became not only physician but surgeon. In other words, the physician who, made this branch of his profession his special study in most general hospitals, now operate upon their own cases without calling in the aid of the general surgeon. And surely this is as it should be. I would ask where would gynæcology be now if it had not been for the work done at special hospitals? Would Sir Spencer Wells ever have achieved the success which has immortalised his name for ever? Ovariotomy introduced by Clay and Baker Brown and Sir Spencer Wells had, in its early days, a mortality of some 90 per cent., whereas now it has been reduced to something under 5 per cent. Would the important discoveries and contributions of Sir J. Simpson to the foundation of gynæcology ever have been made? or the brilliant results of Bantock, Keith, Tait, Knowsley Thornton been attained. What made the names of Battey and Emmet famous but the knowledge they obtained at special hospitals. It will be observed I refrain from touching upon the knowledge acquired by other London hospitals from special hospitals. The eye, the throat, the ear, all of which were founded before these subjects became a special study at the general hospitals.

Such was the growth of gynæcology that in the year 1858 the profession found it impossible to discuss with advantage the subject at the Medical or Med Chir. Societies, and hence the Obstetrical Society was founded as an off-shoot. This society has always done, and is still doing, excellent work, and all-sufficient to meet the demands of the special department for which it was instituted; but such, however, was the rapid strides made in gynæcology that in the year 1884, ten years ago, it was deemed by a number of prominent and leading gynæcologists absolutely essential for the thorough discussion of gynæcological surgery that more time should be available for the reporting its progress, exhibiting specimens, and the reporting of cases than was possible at the Obstetrical Society. And here let me remark that this Society was founded in no antagonistic spirit to the parent Society, but merely on account of its being found impossible, in the compass of the meetings of two hours each, to include all that was going on both in obstetrics and gynæcology, and it was felt that a large quantity of most valuable material was being lost by so short a time being devoted to the subject. What has been the result? Have the results proved or not that this society was needed? Reference to the *British Gynæcological Journal* will, I think, show that if the Society had not existed much valuable work which has been performed by prominent gynæcologists would have been lost to the profession. To attempt to pass in review what has been done in these ten years would occupy far too much time for me to attempt to enumerate here. Incidentally I may mention that the pathology and operative treatment of tubal gestation, improvement in the treatment of the stump in abdominal hysterectomy, the treatment of cancer of the uterus, vaginal hysterectomy, supra-vaginal amputation have all been the outcome of the discussion at the meetings of the Society, and have been the means of greatly increasing our knowledge and establishing gynæcology on a sound and permanent basis.

(a) Address delivered January 18th, 1894.

ON THE
TREATMENT OF INFLUENZA,
WITH ESPECIAL REFERENCE TO THE USE OF DIGITALIS AND ACONITE.

By WM. E. BURTON, L.R.C.S., L.M., T.C.D.

As this paper is not concerned with either the etiology or bacteriology of influenza it is unnecessary to allude to the investigations which have been undertaken in these directions, and which have not as yet, so far as I am aware, resulted in the discovery of any satisfactory method or principle of treatment.

It will, however, be convenient for practical purposes in the present state of our want of knowledge about the sources and causation of the disease, to differentiate those so-called "forms" usually met with, so as to facilitate the explanation of the treatment I am about to describe.

I.—*Typical Influenza.*—This form is uncomplicated throughout and presents the following symptoms, viz. :— 1. Fall of temperature for usually 24 to 36 hours at least, sometimes 3 days (frequently this fall is much shorter or unnoticed). 2. Rise of temperature, usually extremely rapid, and almost concurrently with this. 3. Headache, more or less severe and affecting either the whole head or, more generally, the occiput or sinciput. 4. Dorsal pain, often severe. 5. Pains in the limbs, sometimes like "flashes of fiery heat." 6. Delirium, frequently but not usually. 7. Insomnia. 8. Great nerve prostration, and (probably a result of this) 9. Muscular debility. 10. Nausea, sometimes sickness. 11. Injection of the conjunctiva *without overflow of tears.* 12. Painless inflammation or hyperæmia of the mucous membrane of the tonsils or pharynx.

Here I wish to state my belief, based on close observation of a very considerable number of cases occurring in the last four epidemics, that all other "forms" of influenza than that just described are those in which either a secondary affection is developed in a patient already the subject of influenza, or in which influenza itself attacks a patient previously weakened by some catarrhal affection. I admit that in the winter months (when influenza is most rife) one meets few cases which have not catarrhal symptoms. These symptoms, however, are, I maintain, the result of exposure to cold, and may precede, accompany, or follow, the influenzal invasion.

II. *Influenza intercurrent with disorders of the respiratory tract,* as :—(*a*) Coryza, (*b*) bronchial catarrh, (*c*) pneumonia, "idiopathic" or "catarrhal," (*d*) pleurisy, &c.

In this form (so common in the winter months, especially when the atmospheric pressure and temperature vary frequently and considerably) the catarrhal symptoms are assumed by most writers to arise from influenzal poisoning. So that it is not at all uncommon for a patient suffering from an attack of catarrhal bronchitis, &c., to be treated for influenza, recover, and within a few days to be attacked with typical influenza, *i.e.*, without any catarrhal symptoms whatever.

III.—*Abdominal Influenza.*—In this variety there is from the first evidence of severe gastro-intestinal disturbance, as :—(*a*) thickly-coated, creamy, moist tongue, (*b*) sickness or nausea, (*c*) anorexia, (*d*) diarrhœa, sometimes choleraic, (*e*) constipation. In this form there is usually either very little fever or even subnormal temperature, although there may be, and usually is, severe cephalalgia, &c.

In addition to the complications or varieties already noticed there are several affections any one or more of which may be intercurrent with influenza, such as, acute arthritis, nephritis, metritis, median otitis, &c., each of which, as a rule with few exceptions, clears up with the temperature-fall which follows my treatment. Median otitis, however, is sometimes very formidable and needs energetic local treatment.

I.—1. In the treatment of typical, or indeed, any form of influenza, the patient should be isolated, preferably in a darkened room sufficiently airy. The room temperature should be maintained at from 63° F. to 65° F. The bedclothes should consist of sheet and blankets, no counterpane, and should be graduated in thickness inversely to patient's temperature. Patient's feelings may be considered to some extent on this point, but it is well to remember that the feeling of chilliness which often accompanies very high temperatures is relieved by cooling the surface. (It is common to find a patient with a temperature of over 103° F. or 104° F., and rising, covered with a sheet, three or four blankets, a cotton counterpane, and an eider-down quilt.)

2.—From the first the patient must be saved all possible exertion : this point is of the utmost importance during treatment.

3.—The horizontal position should be insisted on and when it becomes necessary to raise the patient to a sitting posture, this should be done deliberately and gently.

4.—The feet should be frequently examined by the nurse as they are often cold at first : even when the temperature by the mouth is high.

5.—*The Diet*, from the first, should consist of cold milk, plain, or mixed with an equal quantity of barley or soda water. (Beef tea and other meat infusions have never satisfied me during the pyrexial stage, when rapidity of the heart's action is so noticeable a symptom.) Plain boiled water may also be taken cold at intervals; but this should not take the place of milk. I have not found it necessary, hitherto, to give alcoholic stimulants during the pyrexial stage although later on they are most useful. Alcohol distinctly antagonises the slowing effect of the remedies on the heart's action, and, in this regard, materially retards the antifebrile influence of the aconite and digitalis.

6.—The patient should be kept free from all excitement, and should be spoken to as seldom and as little as possible.

7.—Directly the patient has been placed in bed, I give the following mixture to an adult suffering from typical influenza :—

℞ Succi digitalis, ♏ x;
Tr. aconiti, B.P., ♏ ijss;
Liq. ammon. cit., f ʒijss;
Aquam ad f ℥ss M. et mitte f ℥viij.

et signn. "Caution. One tablespoonful to be taken directly, and repeated every hour until four doses have been taken : then every two, three, or four hours as directed."

If there be a marked and pretty rapid temperature fall (say from 104° F, to 102° F, in the first four hours) it may not be necessary to give the fifth dose until three or four hours after the fourth. In deciding this point, regard must be had to the effect of the drugs upon the heart's action, which should have been carefully examined in the first instance. I say this as a matter of precaution : although, out of many hundred cases, I have not met with one in which the drugs had other than a beneficial effect. As a rule I find it advantageous to push the digitalis steadily, every two hours, after the fourth dose has been taken, until the temperature has fallen to 99°·4 F, or 99° F, when it should be discontinued. Under this treatment the temperature falls, in the great majority of cases, to 99° F. or lower, within twelve hours from the time the first dose is taken and—what is very noticeable—does not rise again above normal. Frequently it reaches normal, or lower, in six hours or less. In one typical case (*i.e.*, without discoverable complications) the patient (a robust healthy man, æt. 23,) had his temperature reduced from 105°·6 F. to 98°·1 F. in seven hours. He had been taking (owing to the culpable negligence of the attendant) double the dose prescribed (or digitalis ♏ 20 with tinct. aconite ♏ v) every hour. This patient felt well but weak after the seventh dose, and recovered quickly.

II.—In the cases preceded or accompanied by the lighter catarrhal symptoms, precisely the same form of treatment is adopted. If the catarrhal affections (cough, sneezing, &c.,) are troublesome, a menthol spray (used at intervals of two hours, more or less) gives great and immediate relief. Especially it would help to prevent the spread of the poison through the Eustachian tube to the tympanum, as so often happens in cases of this class. If the tympanic cavity should be attacked, the most energetic measures should be taken without delay. If there be much pain, and especially if the tympanic membrane looks red and inflamed, a leech to the tragus will give relief; but it is safer in every case of "influenza ear" to have the help of an aural surgeon.

Influenza complicated with (*a*) Pneumonia; (*b*) Pleurisy; (*c*) Lung congestion (especially in cases of weak heart).

In the management of these cases the treatment indicated in Class I may unhesitatingly be carried out *when there is a high temperature with a rapid pulse*, if the patient be seen early enough. Even where the inflammation has either been unnoticed, or has spread in spite of previous treatment, it is remarkable how distinctly and quickly it yields to the aconite and digitalis. The presence of cardiac weakness or disease does not contra-indicate the use of digitalis, which seems rather to strengthen than weaken the contractions of the heart. In several cases of dilated heart and fatty degeneration of heart it was noticed that, while the contractions were rapidly slowed, the impulse became distinctly stronger. Aconite may be given in some cases of valvular disease where the heart muscle is robust and the blood stream not appreciably interfered with; but, as a rule, when there is heart complication, it had better be omitted altogether, or, if given at all, withdrawn early (*i.e.*, after the first four or five doses). To make up for its withdrawal, however, larger doses of digitalis may be safely given as long as the temperature remains high. Along with digitalis and aconite in full doses a hypodermic tabloid of ergotinin may be placed every two hours under the tongue, where it is quickly absorbed. This combination has the effect of producing speedy resolution in the large majority of instances. I have met only two exceptions. Of course the pulse slows more gradually and the temperature falls more slowly in patients suffering from such a serious complication as pneumonia than in those with the typical disease. The only form of ammonia I have found useful is the citrate solution in ʒiiss doses, and I give it chiefly for the sake of its action on the respiratory mucous membrane. One gives this drug as routine practice in so many febrile disorders that one may easily induce oneself to believe in its efficiency. I am convinced, however, that diaphoresis will not reduce pyrexia. It is, for instance, not unknown that profuse sweating accompanies a rapidly rising temperature; as in a case, some years ago, in which the patient had double pneumonia affecting the entire right lung and base of the left; and where, with colliquative diaphoresis, the temperature had risen rapidly from 108°·6 F. (when I first saw him) to 113°·5 F. when he died. As to other drugs for reducing temperature, such as antipyrin, antifebrin, phenacetin, the various forms of quinine (including ammoniated tincture of quinine), periodate of calcium, &c., they have not satisfied, in any one particular, the expectations I had been led to form of them. Where the temperature has been temporarily lowered by these drugs it has invariably risen again. Also the patient soon developed toxic symptoms of a more or less important character from their action, without their shortening the illness in any appreciable degree. Here again I must strongly advise entire abstention from alcohol as a rule, provided the patient be seen early enough to secure that the advance of the pneumonia has not involved a considerable amount of lung. Occasionally one is called in too late in these cases; but usually they are seen early enough to allow of the treatment being carried out without recourse to alcohol in the pyrexial stage. Where alcohol is needed (where there is a rapid and jerky pulse) it should be given with a free hand, especially to those accustomed to its use. Brandy is best in the pyrexial stage; champagne later on. While the surface of the body should be protected from cold by moderate coverings, I have seen nothing but harm come of hot applications, poultices, cotton wool, &c. Leiter's tubes and ice-bags may perhaps be useful in the more sthenic forms, but I cannot say, after a pretty extensive trial, that I am entirely satisfied of their efficacy.

Where the lung is largely invaded, oxygen in Brin's tubes is useful if given freely and frequently. In such cases the nurse should be instructed to repeat the inhalations at least every half hour, oftener if the respiration is shallow and very hurried. Each inhalation should occupy from two to five minutes or longer as may be required. Purgatives should be given with caution if at all. My experience is that the less the patient is distressed by the exertion of passing a motion the better. Castor oil is the best aperient.

(*b*) Pleurisy of the sthenic type, intercurrent with influenza, should be treated internally by digitalis and aconite in the doses already mentioned—if seen in the first stage. Externally sinapisms seem to relieve the pain, and lessen the inflammation. These cases are usually well in two or three days. Where, however, they are seen too late to avert the second stage, the usual local treatments must be had recourse to. Asthenic pleurisy is rarely, if ever, to be found concurrently with influenza, and when it is present requires only the ordinary treatment.

III.—Abdominal Influenza.—There are two classes into which, for the purposes of treatment, abdominal influenza may be divided, viz.:—A. Those cases in which gastro-intestinal irritation appears concurrently with typical influenza, and in which there is, with other symptoms, a high temperature. In these I adopt the antipyretic treatment already described, and give, in addition, 7 grains of salol crystals, on the tongue, every five hours. The diarrhœa is seldom troublesome, and when it does occur appears to be critical and to terminate after one or two very copious actions of the bowels. I have never found it necessary to check this action. B. *Abdominal influenza, which is without fever, and, generally, with a subnormal temperature; but in which there are all or most of the other symptoms of typical influenza.* Severe, almost choleraic, diarrhœa frequently occurs in this form of the disease, which may safely be treated on general principles. I have found salol in from 5-grain to 7-grain doses every four hours most useful in cases of this variety. It is, of course, unnecessary to give either aconite or digitalis in the absence of febrile symptoms.

In addition to the complications already noticed, there are many others, such as nephritis, metritis, cystitis, acute rheumatism, &c., which, with the exception of cystitis and acute rheumatism, need little, if any, modification of the treatment. In cystitis the usual routine treatment will be found enough for the local trouble, and in no respect contraindicates the use of digitalis and aconite. Acute rheumatism complicating influenza almost always yields rapidly to a combination of salol and phenacetin (5 grains of each) every four hours. In these cases the aconite should be withdrawn if phenacetin be given; but while pyrexia is present, the digitalis should be continued in 10-, 15-, or 20-minim doses every hour (according to the strength of the circulation) until a decided effect is produced on the temperature.

Short notes of a few illustrative cases will serve to exemplify the treatment usually adopted by me, and its results. The cases are taken from the very brief notes of each I was able to make during the height of each epidemic.

Case 1.—T. W., æt. 25, male. Acute double basic pneumonia, involving the posterior of both lungs—to the upper edge of the eighth rib on the left side, and to the lower edge of the seventh rib on the right side. No friction sound. No appreciable pleuritic effusion. Considerable pain especially on the right side. Characteristic cough. No expectoration. Face flushed. Breathing 54, pulse 120, temperature (under tongue) 104·6 F.

Ordered:—

℞ Succi digitalis, ♏x;
Tr. aconiti, ♏ijss;
Ext. ergot. liq. am., fʒss;
Liq. amm. cit., fʒijss;
Aquam ad, ℥fss.

M. et mitte f℥viij. et. sig. "Caution. A tablespoonful by measure-glass to be taken directly, and repeated every hour until 6 doses have been taken, then every two hours."

℞ Brin's oxygen cylinder
with mask

"Oxygen to be inhaled every half-hour for 5 minutes each time."

Diet—Milk *ad. lib.*, cold or hot as preferred. Absolute rest as far as possible. Six hours after the first dose the temperature had fallen to 104° F., and, thereafter, the temperature registered at successive periods of 4 hours each 103°·2 F, 102°·9, 102°·8, 100°·6, 101°·4, 101°, 100°·2, 100°·1, 100°·4, 100°, 100°, 100°·2, 99·8, 99°·9, &c. The temperature, it will be noticed, ceased to be formidable by the end of the first 24 hours; and with the exception of one slight rise, due to accidental exposure, never rose much above normal afterwards. The lungs gradually recovered until they were quite free by the 12th day from onset. There was no expectoration of importance throughout. When the temperature had fallen to 100°·6 F the aconite was stopped, and the digitalis given at 4 hours intervals, for eight hours longer, when it also was stopped.

This patient had, during the first 24 hours, slight but unmistakable symptoms of acute rheumatism. (He had twice previously suffered from rheumatic fever.) This was not specially treated, and passed off by the end of the second day.

Exactly one week after complete recovery, he insisted in my absence on going for a walk out of doors in a severely cold easterly wind; and had a second attack of double basic pneumonia. He was seen before the inflammation had spread more than inch above the margin of either lung. Precisely similar treatment was adopted, and the patient was well in six days. As the after-treatment of this case is fairly representative of my usual routine it is given here.

Diet.—Milk exclusively till the temperature fell below 100°·5 F., when beef tea or chicken broth containing a teaspoonful of Valentine's beef juice or part of a beaten egg was permitted, also a little dry toast. When the temperature fell below 99°·5 F., beaten eggs with milk and a teaspoonful of brandy or equivalent of port wine, a little boiled fish, tea, bread and butter, milk pudding. Next day, chicken with champagne or claret, &c., and thereafter a rapid return to the ordinary diet; also this tonic:—

℞ Ferri phosph., gr. v;
Acid. phosph. dil., ♏ v;
Tinct. nucis vom., ♏ x;
Tinct. calumbæ, f℥j;
Aquam, ad f℥j.

M. et mitte f℥viij. et sig.: "An 8th part to be taken three times a day (after meals) for six weeks.

CASE 11.—S. F., 51, robust, active man. Has excellent health. After driving some hours in a dogcart had a severe rigor, followed almost directly by vomiting, cephalalgia, pain in back and limbs, and delirium. When seen face was flushed, eyes suffused (no overflow of tears), violently maniacal, shouting incoherent sentences, and was restrained with difficulty. About three ounces of deep red urine had been passed an hour previously; it contained no blood, and only a trace of albumen. Temperature (which was not satisfactory), taken in axilla 104°·3 F., probably much higher. Pulse 124, full and bounding. Ordered:—

℞ Succi digitalis, ♏ xv;
Tinct. aconiti, P.B., ♏ ijss;
Aquam, ad f℥ss.

M. pro dosi j, et mitte f℥viij, et sig., "A tablespoonful every hour until four doses have been taken, and then every two hours."

The temperature fell, in successive periods of four hours each, to 103°·2 F, 103°·1, 102°·8, 102°·6, 100°·8, 99°, 98°·1. Thereafter patient was and continued well.

The trace of albumen which was present was more marked on the second and third days, but eventually completely disappeared.

CASE 22.—V. S., æt. 5, female. A delicate child. Mother phthisical. Patient had been suffering from "a bad cold" for some days. Face flushed. Respiration 60. Pulse feeble, 134. Temperature 105°·6 F. Cough frequent and distressing; pain in right chest; urine dark, scanty, no albumen. Patches of tubular breathing over left lung, but no perceptible dullness; distinct dullness over right mammary region, reaching to a finger breadth above the anterior base and strongly marked bronchial respiration.

Directions.—Keep room temperature at 63° F. to 65° F. Cover patient with one sheet and one blanket only. Keep the feet warm. Save patient exertion as much as possible. Give milk (cold or warm as preferred) frequently.

℞ Tinct. aconiti, ♏ x;
Aquam, ad f℥ij. M. et sig.:

"No. 1.—Give one teaspoonful mixed with one teaspoonful of No. 2, every hour till temperature begins to fall steadily; then discontinue this medicine."

℞ Succi digitalis, ♏ xl;
Liq. ammon. cit. f℥iv;
Acidi citrici, gr. x;
Syr. limon., f℥j;
Aquam, ad f℥ij. M. et sig.

"No. 2.—Give a teaspoonful every hour for four or five hours, and then every two, three, or four hours, according to directions."

The temperature registered in successive periods of four hours each, from 105°·6 F. to 105°·8, 105°·1, 104°·6, 103°. After the tenth dose the aconite was stopped, but the digitalis was continued in full doses every two hours, for it was well borne. The heart's action certainly became stronger under the influence of the drug, and its rapidity lessened. By the end of 24 hours from the commencement of treatment, the temperature had steadily fallen to 102°·8.; the last six doses of digitalis being given every four hours. During the next 24 hours the digitalis was given every six hours and omitted when the child slept. At the completion of 48 hours the digitalis was stopped, and a mixture containing quinine (½ gr.) and tinct. nux vom. (2½ ♏.) substituted. The temperature did not rise subsequently, to any noticeable extent, and by the end of the third day (72 hours) had fallen to 99°·8 F. Thereafter the recovery was uninterrupted. For several days after the temperature had fallen to normal, she was kept lying down in bed.

CASE 27.—G. S., æt. 40, strong healthy woman. Attacked with severe influenzal symptoms one hour before being seen, when she had severe occipital cephalalgia, pain in back and limbs, nausea, anorexia, &c. Temperature under tongue 104°·1 F., Pulse 126. Tongue clean, moist; slight pharyngitis; eyes suffused, but no overflow of tears—a typical case of uncomplicated influenza. Treatment precisely as in Case 11. Temperature fell four-hourly from 104°·1 F. to 103°·2, 101°·1 100°·, 99°·6, 98°·2, and did not subsequently rise above normal.

CASE 30.—R. M., æt. 7, male; well nourished, well developed. Influenza (uncomplicated). No catarrhal symptoms whatever. Face flushed; eyes suffused, no overflow of tears; tongue clean, moist; headache, backache, pain in limbs. Temperature 104°·7 F. before treatment, which was same, *mutatis mutandis*, as in Case 11. Temperature fell in successive four-hourly periods from 104°·7 F. to 103°·, 101°·1, 100°·2, 99°·1, 98°·4. Recovery rapid and uninterrupted.

CASE 31.—T. M., æt. 6, brother of preceding. Similar symptoms (uncomplicated influenza). Temperature (immediately before treatment 102°·8 F.) fell, after similar treatment to that of Case 11 to 102° F., 100°·4, 99°·, 98°·4.

The foregoing memoranda (which have been selected as giving a fairly average representation of my routine treatment of influenza) are only a few out of some hundreds (532), of which short notes have been kept.

It may not be out of place to give here some of the considerations which influenced me to decide upon the treatment of influenza by the methods I have endeavoured to set forth as clearly and fully as the necessarily limited space at my disposal would allow.

In observing the results of each of the various treatments advocated during the epidemic of 1889-90 I became convinced that the drugs then in use by others and by myself had no appreciable effect in shortening the duration of the disease in any instance. In other words influenza, untreated, seemed to continue the same course as when quinine in various forms, antipyrin, phenacetin, antifebrin, &c., were freely used. The same course, that is, if we except the slight and *transitory* lowering of the temperature by one or more of these preparations. I noticed that the fall of temperature (gained by the use of these medicines) was quickly followed by a rise after they had been discontinued for a period, which varied according to the severity of the illness and the nature or doses of the remedies. Also, while the heart-contractions were lessened in force in a marked degree by these medicines, and there resulted, in many cases, a cyanotic condition, the frequency of the pulse was increased; in some cases startlingly so. It was evident, moreover, that the protracted convalescence of patients who had undergone such treatment was due quite as much to the toxic effects of the medicines as to the malady itself.

Having these facts before me, and feeling satisfied from repeated experience that the nervous system was primarily and chiefly affected by the virus of influenza, and that in by far the greater number of the *uncomplicated* cases, there appeared to be no observable sequelæ, with the single exception of asthenia, I was led to the following conclusions:—The toxic action of the influenzal virus produced rapid and violent heart-contractions. The pyrexial condition was in a high degree associated as effect with the pulse frequency. Any drug, or combination of drugs, which would safely control this wasteful and—so far as one could see—purposeless expenditure of energy might, *pari passu* with a slowing of the pulse-rate, lessen the temperature and shorten the course of the disease. Aconite at once occurred to me as likely to fulfil both of these requirements. Aconite, however, weakens the heart-contractions when given in sufficiently large doses to cause slowing. Digitalis antagonises aconite, while it, also, has a powerful effect in lessening the pulse frequency. A combination of aconite and digitalis—the latter given in fairly full, and the former in moderate, doses—might be relied upon to secure the end in view if administered with great care.

My results, as given in the cases already mentioned, may prove nothing more than that I was justified in giving the treatment a trial, but I claim they do that. The more I see of the effects of this combination in all acute inflammatory disorders, the more convinced I am that it is wiser, where one can, to control the riotous dissipation of energy implied by, and resulting from, over-excitement of the circulation in such cases.

Out of a total of considerably more than 800 cases of influenza treated by me during the last four epidemics, I have not had a single death from the time I began the digitalis-aconite treatment, yet among these cases were patients suffering from very formidable complications, both acute and chronic. In cases of weak heart, fatty degeneration of heart and valvular diseases it was especially noticeable that the remedies which were strong enough to slow the contractions did not appear to impair very materially the irritability of the heart-muscle, and though it is needless to say that in all such cases there is ever a good deal of anxiety when one considers the extra strain put upon the heart during severe febrile disturbance, yet an extended experience assures me that the physiological action of the remedies is less harmful than the effects of the disease for which they are administered. Doubtless there are cases in which one is called in too late to permit of their being used with likelihood of success—cases, for example, of pneumonia which has already entered the third stage, and in which all one can do is to support the patient's strength by every means. *But in all cases of acute inflammatory diseases, when seen in the earlier stages, digitalis and aconite combined should prove useful if cautiously and intelligently administered.*

In conclusion, I may be permitted to say that the treatment advocated in this paper occurred to me late in December, 1889, and that early in January of the following year, 1890, I began with extreme caution to carry it into practice. In the early part of May, 1891, I mentioned the subject to Dr. Octavius Sturges, and to several other friends. I am desirous of making this statement lest the late appearance of my paper might make it seem that I was making use of the digitalis treatment (in pneumonia only) suggested by Petresco, Murphy, Fikl, &c., whose reports on the use of digitalis (without aconite) I had not seen when I began this paper in January of the present year, as they appeared only, so far as I am aware, in American and German journals in May and June, 1891. I trust that those who have not previously tried the digitalis-aconite treatment may be induced by what I have stated in this paper to give it a fair trial in suitable cases It should always be given with caution, and carefully watched in every instance.

◆

Selected Prescriptions and Therapeutic Notes.

38.—Typhoid Fever :—

Naphthol *a*, gr. x ;
Salicylate of Bismuth, gr. vj ;
Bromohydrate of quinine, gr. iv.
For one wafer. Four to six daily.
From our French Correspondent.

39.—Chronic Rheumatism :—

Salicylate of soda, } ʒij ;
Iodide of potassium, }
Syrup of orange, ℥ij ;
Water, ℥iv.
Four teaspoonfuls daily in water.
From our French Correspondent.

40.—Local Applications in Uterine Cancer.—Powders constitute the best local disinfectant application in the treatment of uterine cancer. They are comforting and relieve at once the vulvar irritation caused by the discharges, which no attention to cleanliness, however careful, can secure. The following disinfectant and caustic powder is useful :—

℞ Iodoform, ℥ijs ;
Cupri sulph, ʒij ;
Morph. sulph., ℥j.
M.

Or when the caustic action is not required the following may be employed :—

℞ Salol, ℥j ;
Lycopodii ;
Tannin, āā, ʒiss.
M.

Or the following :—

℞ Iodoformi, ℥ss ;
Quinine sulph., gr. xxx ;
Pulv. carbonis, ℥j ;
Ol. menth. pip., ♏ x.
M.

The above powders must be applied with the speculum, and the part, after having been dusted with them, must be covered with a plug of iodoform gauze. This dressing might be left for forty-eight hours.—Dr. A. Lutaud.

41.—An Agreeable Laxative :—

℞ Sodii phosphatis, ℥j ;
Tinct. aurantii, ʒij ;
Syr. simplicis, ℥ij ;
Aq. destill, ad ℥viij.
M. Two tablespoonfuls for a dose.

42.—For Acute Coryza :—

℞ Acid carbolic ;
Liq. ammoniæ fort, aa ʒijss ;
Alcohol, ʒv ;
Aq destill, ad ℥j.
Inhale from several drops upon a piece of blotting paper.—Dr. Hayem.

43.—Therapeutic Value of Chloride of Ethyl Spray.—Dr. Edgar Gaus, of Carlsbad, has used chloride of ethyl spray with success in the treatment of a case of supra-orbital neuralgia, which had persisted for six weeks, and was cured by one application of the spray ; also in lumbago, in migraine, pruritus of the scrotum, and in commencing gouty attacks.

44.—Chloroform in the Treatment of Tænia.—The following has proved useful :—

℞ Sp. chloroformi, ℥j ;
Ol. crotonis, ♏ j ;
Glycerini, ℥j.
M. For one dose. Dr. Græsse.

◆

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Clinical Evening.

Meeting held Friday, Jan. 26th, 1894.

The President, Mr. J. W. Hulke, F.R.C.S., in the Chair.

Living Specimens.

Dr. Sidney Phillips showed a man, æt. 40, who had developed nodules over the ulnæ, &c., in association with a history of rheumatic fever.

Dr. Penrose showed a young man, æt. 21, in an advanced stage of the non-spinal form of idiopathic muscular atrophy.

Mr. **Gould** showed a youth on whom he had performed thoracoplasty.

Dr. **Mott** showed a man, æt. 36, who had developed paraplegia after a severe attack of typhoid fever; also musician who while playing had suddenly lost the power of speaking and swallowing, due presumably to a lesion of the pons.

Mr. H. H. **Clutton** on

THREE CASES OF ENDOSTEAL SARCOMA OF RADIUS.

Case 1.—A myeloid sarcoma of the head and neck of radius in a man, æt. 28, who had noticed a swelling for two years. He was already the victim of chronic kidney disease, and was under the care of Dr. Heggate, of Wellingboro, who sent him to Mr. Clutton. The tumour was successfully removed by resection of the upper 3rd of the radius. He died eighteen months after operation from kidney disease, but without any local evidence of a return of the new growth in the radius, and in the meantime his arm and hand were useful and free from pain. *Case* 2.—A man, æt 58, was sent to Mr. Clutton by Dr. Stone, of Reigate, in July, 1891. For twelve mos. he had had pain and swelling in his left wrist. He had an endosteal growth of lower end of the radius, which was subsequently proved to be a myeloid sarcoma. It was treated by resection of the part affected. A corresponding portion of the ulna was removed at the same time to avoid any lateral deviation of the hand, which would otherwise have occurred. He has now (Jan., 1894) a very useful hand, and with a gauntlet can hold a pot of paint weighing 9 lbs. He is a painter by trade. Shown to the Society. *Case* 3 was a round-celled sarcoma of the lower end of the left radius in a woman, æt. 34, who was sent to Mr. Clutton by Dr. Topping, of Forest Gate, in January, 1890. The history was of nine years' duration, but the tumour was thought to be parosteal or periosteal, and was therefore removed by amputation. The specimen shows that it was an endosteal growth and might possibly have been successfully removed by resection without the loss of the hand. But considering its microscopical character it is, on the whole, more satisfactory that amputation was performed. She has had no return of the disease.

The **President** suggested that the author should lay down the lines upon which he would proceed in distinguishing the cases in which this plan of operation would be likely to prove sufficient.

Mr. **Gould** pointed out that the malignancy of endosteal sarcoma varied within wide limits. He suggested that not only was it unnecessary to remove the bone beyond the seat of the disease, but he added that it might possibly suffice to open up the cavity and scrape thoroughly. He referred to the case of sarcoma of the lower jaw in a young woman in which recovery took place after scraping without recurrence for five years (the patient being still well). The first lower jaw he had excised was for a large sarcoma in a man, and there had been no recurrence for ten years.

Mr. **Charters Symons** asked why the ulna was also removed, and mentioned the case of a girl, æt. 11, with sarcoma of the jaw which had been treated by scraping, without recurrence since.

Mr. **Eve** suggested in reference to the means of determining the malignancy of these growths that the more malignant among them distended the bony walls of the cyst irregularly. He did not believe that the histological characters should be relied upon to show the degree of malignancy.

Mr. **Bland Sutton** pointed out that if the ulna were not shortened after resection of the radius a useless hand would be left.

Mr. **Clutton**, in reply, said that it was usually held that the longer the duration of the tumour the longer would the patient probably live whatever the treatment adopted.

NEPHRECTOMY (SUCCESSFUL AFTER FOURTEEN MONTHS) FOR MALIGNANT TUMOUR IN A PATIENT UNDER TWO YEARS OF AGE.

Mr. **Malcolm** related the case of a child, 23 months old, of good family history, strong, and well developed. She was said to have had a "full belly" when she was a year old, and a definite "lump" in her side had been noticed six months later. This lump had steadily grown till it formed an elastic, oval, well-defined tumour, painless, and scarcely, if at all, movable. It filled the right loin extending well down towards the pelvis and just beyond the middle line below the navel. The child was slightly anæmic, but her general health was good, and there was nothing abnormal in the urine. On November 15th, 1892, the abdomen was opened through the right linear semilunaris, the kidney on the other side was examined and found apparently healthy, and the tumour was removed through an incision in the posterior layer of the peritoneum immediately to the outer side of the ascending colon which passed in front of the growth. The greatest care was taken not to open the capsule of the kidney which also included the tumour, but some of it was inadvertently separated during the enucleation of the deeper part. When the growth was got out of the way, the remaining shreds of its capsule and a mass of glands and fat surrounding the right renal vessels were also carefully removed. The divided end of the ureter was brought outside the skin, and the wound was closed without drainage. During convalescence, the highest temperature and pulse, namely, 101° F. and 144 respectively, were recorded the day after the operation. By the end of a week, fever was practically gone. The wound healed well, and except the presence of a little albumen in the urine the first night, there was nothing of importance to record. A year later the urine was examined and nothing abnormal was detected in it. On the 25th of this month Dr. Marshall, of Barnes, reported that the child "is in perfect health." The tumour was of oval shape and measured six inches by four inches. The posterior half of the kidney substance was apparently healthy. The anterior half was partly replaced by, and partly expanded for a short distance over the new growth. The tumour was described by Mr. Targett as a "malignant adenoma," separated from the kidney by a capsule of dense fibroid tissue and consisting of tubes lined by epithelial cells with a scanty and exceedingly delicate stroma, but with strands of connective tissue dividing the field into large loculi. Examination of the glands by Mr Targett and Dr. G. M. Callender did not show conclusive evidence of secondary deposit in them. It was pointed out that the records of nephrectomy for neoplasm in children show an immediate mortality of over 50 per cent., while those that survived the operation had all died within a year, only one exception [Hicquet, quoted by Bruce Clarke, Surgical Diseases of the Kidney, p. 54] having been found, in which case the patient survived for 18 months. The operator therefore scarcely hoped for a complete success in his case although the patient had now lived more than fourteen months after the operation and was quite free from any signs of recurrence. Attention was directed to the advice of Mr. Godlee [Clinical Society's Transactions, 1884,] that operation should be performed in a number of cases of small tumour, at an early date before we decide whether nephrectomy in children should be considered an altogether unjustifiable operation, and it was pointed out that the records did not seem to indicate that the removal of small tumours had been specially successful. Mr. Malcolm inclined to the belief that clinical histories might be associated with structural differences in the tumours which render some more suitable for surgical interference than others, even at a comparatively advanced stage of their growth. He hoped that future observations might enable us to differentiate beforehand those cases in which it may be expected that life could be prolonged by operation. It was noted that the tumour shown was described by Mr. Targett as a "malignant adenoma," but that in Mr. Bland Sutton's book on tumours such growths seem to come under sarcomata. Mr. Malcolm thought the specimen he exhibited could scarcely be called a connective tissue neoplasm. He believed that the tumour was not exactly similar to any hitherto removed during life and described. It was suggested that in some peculiarity of structure in the tumour might be found the explanation of the prolonged immunity from recurrence. While inclining to this view, the author pointed out that the method of operating is of the greatest importance, and that the careful removal of the glands is to be recommended when practicable. He opposed the advice of Mr. Henry Morris and Mr. Bland Sutton that solid tumours of the kidney should be removed from within their capsules. To cut as widely of the disease as possible was held to be the only scientific method, and the only way by which we could hope to improve the results of the operation in the future. The author advocated the adoption of the plan of bringing the cut end of the ureter outside the skin, as recommended by Mr. Knowsley Thornton. He considered this as important from the view of the antiseptic surgeon as removing the capsule is essential from the view of the pathologist.

On the motion of Mr. **Bland Sutton**, who urged that the subject was too important to be disposed in a few minutes, the discussion was postponed until the next meeting.

◆

OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN.

Meeting held Thursday, January 25th.

The President, Dr. **Argyll Robertson**, in the chair.

ANEURISM OF THE ORBIT.

Mr. E. **Clarke** showed a child, æt. 3, with proptosis and pulsation of the eyeball. He concluded that it was a case of aneurism behind the globe, and suggested ligature of the common carotid as the appropriate treatment.

The **President** related two well-marked cases of the kind, of traumatic origin, both in children, which had been cured by electrolysis.

Dr. **Stephen Mackenzie** mentioned a case which had subsided under medical treatment.

Mr. **Jonathan Hutchinson** referred to a case in the country in which it was proposed to ligature the carotid, but the tumour disappeared under large doses of iodide of potassium.

Dr. **Eales**, of Birmingham, related the case of a miner lad, who, after a crush of the head, developed symptoms of arterio-venous aneurism of one eye, with proptosis, murmur, and the characteristic thrill. He had felt inclined to ligature the carotid, but when he showed the case at their medical society, the surgeons were opposed to such a course, and operative interference was postponed until the next meeting. In the interval the tumour subsided and finally disappeared.

Mr. **Carless** pointed out that it was necessary to distinguish between congenital cases, like the author's case, and those of traumatic origin. He mentioned a case of pulsating tumour of the upper eyelid in a man, which had subsided under a pretty strong application of the constant current. He pointed out that ligature of the carotid in young children was usually a fatal operation.

Mr. **Hill Griffith**, of Manchester, suggessed that the tumour might possibly be a meningocele.

SCHOOL OPHTHALMIA.

Mr. **Jonathan Hutchinson** read a paper on "School Ophthalmia," of which we publish a full abstract elsewhere.

Dr. **Sidney Stephenson** referred to what had been done in the way of providing isolation schools for children suffering from this form of ophthalmia, and dilated upon the difficulty in keeping children in the schools until all danger of their infecting others had been averted. He admitted that when he first directed his attention to the treatment of these cases he believed the follicular bodies to be the first stage of trachoma, but subsequent experience had convinced him that this was a mistake. An investigation of the condition of the eye in upwards of 14,000 children had shown him that follicular changes were present in 94·5 per cent. of school children other than those in pauper schools, so that he felt disposed to regard them as normal to the majority of children, and he doubted their relationship to granular disease.

Mr. **Rockliffe**, of Hull, said he had been called upon to advise in several boys from one of the schools alluded to by Mr. Hutchinson, and he had failed to discover any appearances that in his opinion would justify the diagnosis of incipient granular disease. In most instances the boys said there had been no discomfort, no photophobia, and indeed, they had not been aware of anything being the matter until the doctor said there was. He believed that the form of ophthalmia described by the author was a distinct affection not allied to granular disease.

Mr. **Nettleship** thought the author had taken an extreme view of the condition alluded to. Outbreaks of mild ophthalmia occurred in all kinds of schools, but he doubted whether this had anything in common with granular disease. If this were the case, however, he agreed that the sooner they burst the bubble the better. If granular disease were really increasing in their midst, as the author suggested, surely they would have met with cases in lads who had gone through some of the higher schools, but as a matter of fact such cases were very rare. In view of the admitted difficulty of diagnosis between healthy and morbid eyes in this respect, he urged that during the prevalence of ophthalmia every suspicious case should be carefully watched. The most valuable test of a morbid condition of the conjunctiva was a certain amount of sticky discharge.

The discussion was adjourned until the next meeting.

◆

THE HUNTERIAN SOCIETY.

Meeting held Wednesday, Jan. 10th.

The President, Mr. F. **Gordon Brown**, in the Chair.

Dr. **Fletcher Beach** read a paper on

SPORADIC CRETINISM.

After giving a short history of the subject, he stated that the observations in the paper were chiefly founded on an analysis of 116 cases, including 16 which had been under his care, collected from various sources. He mentioned that the disease was present in the fœtus, and that the cases formerly defined as fœtal rickets were not known to be cases of sporadic cretinism. He described the condition of the body, thyroid gland, and fatty tumours, skull and bones, found in such cases, and alluded to the state of the brain in one of Barlow's cases which showed remarkable features in the temporo-sphenoidal lobes. Sporadic cretinism was also found in calves, sheep, and dogs. The etiology of the disease was then considered, and the influence of consanguinity, intemperance, phthisis, inherited mental disease, neurotic inheritance, and fright of the mother during pregnancy, in the production of the disease, was described. It was shown that the lowest age at which patients had been treated was six months, and the highest 42 years; on the other hand, the symptoms were first noted in 15 cases at or soon after birth, and from that time up to the age of 18 months, 25 were seen. With regard to the sex, so far as the analysis of 116 cases went, in sporadic cretinism, there were not quite twice as many females as males, a different proportion to that found in myxœdema, in which females are four times as many as males. With repect to the locality in which these 116 cases occurred, it appeared that the disease prevailed most extensively in England, and that Scotland, France, and America had about an equal number. The author related the symptoms found in sporadic cretinism, and stated that previously to the report of the Clinical Society on myxœdema he held the opinion that sporadic cretinism and myxœdema were one and the same disease, any difference between the two being due to the different ages at which the two diseases were developed. Sporadic cretinism was due to absence or disease of the thyroid gland, for in some few cases bronchocele had been found to be present. The opinion of Horsley that the thyroid gland had a homopoietic as well as a secreting action was alluded to, and the differences between the changes which took place in the thyroid gland in myxœdema and in sporadic cretinism were mentioned. It was shown that the same fibrous changes which accurred in the tissues of the monkeys operated upon and kept alive by Horsley were present not only in myxœdema and cachexia strumipriva, but also in sporadic cretinism, and a case under the care of the author in which these changes were seen was described. The diagnosis and prognosis of sporadic cretinism were touched upon, and the treatment was shortly mentioned.

Dr. **Walter Ord** mentioned two cases in which he had given 5 grain of the dried thyroid extract daily with marked benefit.

Dr. **Shuttleworth** showed photographs before and after treatment of five cases of sporadic cretinism which he had seen at the Lancaster County Asylum. Of the patients four were females. In two families the eldest and the fourth children were cretins, the seond and third being healthy.

Dr. FLETCHER BEACH, in reply to questions, stated that in his experience most cases occurred in the lower classes, that the number of first-born children affected was not great. In many cases some healthy children intervened between two cretins in one family. The patients were very apathetic, very subject to bronchitis, and had usually a small quick pulse.

Mr. OPENSHAW, with Mr. Waren Tay's permission, read the notes of twenty-two consecutive cases of amputation of the mamma for carcinoma, all of which had united by first intention.

◆

COUNTY AND CITY OF CORK MEDICAL AND SURGICAL ASSOCIATION.

AT the last meeting of this Society, Dr. A. W. SANDFORD, President, in the Chair,

Dr. COTTER read notes on a case of

PAROVARIAN CYST,

and showed pathological specimen of a case on which he had operated successfully. The tumour had existed for 18 months, beginning as a small hard swelling in the hypogastric region accompanied with strongly marked neurasthenic symptoms. It did not increase in size during the following 15 months, but during the remaining three months rapidly reached its present large dimensions. There was a history of menorrhagia and metrorrhagia with more or less pain. Previous to operation the tumour was of an elastic fluctuating character. The progress of the patient subsequently was uneventful and she left hospital in about three weeks, quite well.

Spina Bifida.—Surgeon-Lieutenant WALKER detailed an interesting case which he had cured by injections of Morton's fluid. The tumour was situated over the lumbar, lower dorsal and upper sacral vertebræ, with paralysis of the lower extremities. It was apparent from birth. First injection was given two weeks subsequent after the tumour had been supported by an improvised apparatus. Forty drops were injected after tapping, with the result of diminishing the tumour in 8 days to half its size. It was again tapped and 20 drops injected, and on one other occasion the same procedure followed. The lower limbs rapidly recovered their power and the cleft in the vertebræ became bridged over with a tense membrane and gradual narrowing of this cleft. The maternal history during gestation was interesting, she having been thrown from a cart and severely bruised in the third month; having had during pregnancy severe floodings with constant pain on right side. Mr. Walker considered the successful issue of his case was mainly due to the very rigid antiseptic precautions he adopted, and the carefully regulated support of the tumour.

Hemi-Chorea.—Dr. Wagner read notes of a case of this affection in a female patient, æt. 71.

Intestinal Obstruction.—Dr. Wagner also read a paper and showed a pathological specimen of a case of above, followed by a discussion in which the President, Drs. Cotter, H. R. Townsend, and Surgeon-Captain Deacon joined.

PARIS, Jan. 27th.

TREATMENT OF CHRONIC EMPYEMA.

AT the Academie de Médecine M. Delorme communicated a new method of treating chronic empyema when pleurotomy had not produced a cure. The method consists in the opening of a large extent of the thoracic wall in the form of a shutter, and the ablation of the false membrane which surrounds the lung, binding it to the vertebral sulcus. The lung thus set free, the shutter is closed and the patient gets well as easily from these costal sections as from ordinary fractures of the ribs. The method had been applied recently by the speaker on a man affected with pleurisy of the left side, and who has been treated by pleurotomy without success. The false membrane was fully half an inch thick and covered with fungosities. These were scraped off and the membrane dissected from the lung by means of a pair of scissors guided on a canula. The lung was healthy, and when entirely set free it unfolded itself *brusquement*, and bulged out through the wound. After that the toillette of the pleural cavity had been made with a sublimate solution, the shutter was closed down and sutured. A slight compress of cotton completed the operation. The patient made a good recovery. M. Delorme said that he considered this method superior and more rational than that of Estlander, for when it is followed with success it allows the lung to fill the pleural cavity and to continue its function.

AMBROISE PARE.

It is not generally known that the origin of the great reputation of the father of French surgery, Ambroise Paré, was due to an incident that occurred at the Siege of Boulogne-sur-Mer. The Duc de Guise had been carried to his tent with a fearful wound, produced by the point of a lance. The lance had entered the cheek of the prince under right eye and passed out in the neck under the ear. The weapon broke in the wound. His surgeon, Ambroise Paré, arrived, and said to his assistants: "Gentlemen, the prince is not dead, but he will be soon in the other world unless, regardless of any respect for his person, I pull out at once this shaft from his head." Planting his foot on the face of the prince (!) he seized the piece of iron with his fingers, and after a considerable see-saw movement he succeeded in drawing it out. The prince recovered, and bore ever afterwards the nickname of *Balafré*.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 26th.

INCREASE IN THE RANKS OF THE PROFESSION.

COMPLAINTS as to the rapid increase in numbers of medical men continue to grow louder. Although it is already difficult for a great number of doctors to earn a subsistence, their number continues to increase at an alarming rate. The number of medical men in Germany at the close of 1892 was 20,500, whilst at the close of 1893 it was 21,621, equal to an increase of 5·46 per cent. In Berlin at the close of 1892 there were 1,636, and at the close of 1893, 1,799, or an increase of 10 per cent. During the past five years the increase in the numbers of medical men has been 22·2 per cent. In Prussia there are 12,851 medical men, or an increase of 777 on the previous year; in Bavaria, 2,431, an increase of 86; in Saxony, 1,563, being an increase of 40; in Baden, 855, with an increase of 44; in Wurtemberg, 739, with an increase of 28; in Elsass-Lothringen, 632, with an increase of 33; in Hamburg, 429, an increase of 8.

The proportion to the number of inhabitants is 4·37 to each 10,000 of population, against 4·15 in 1892. The Hanseatic towns are the best provided with medical men, Hamburg having 6·98 to each 10,000 of population, Bremen 6·92, and Lubeck 6·11. Prussia, on the other hand, has only 4·28. There is one exception to this, however, and that is the University towns. These have a still greater proportion of medical men than even the Hanseatic towns. In Strassburg there are 17·8 to each 10,000 of population, in Halle 12·1, in Munich 11·9, in Berlin 11·5, in Breslau 11·3, and in Königsberg 10·6. This increasing overcrowding taken in conjunction with the great increase in contract work and general low fees makes the prospects of the profession here anything but brilliant.

The Medical Society.

The annual meeting of the Medical Society was held on the 10th inst., when Prof. Virchow was again elected President, and Profs. v. Bergmann and Siegmund, Vice-Presidents. From the report it appears that the member ship at the end of the year was 914, as compared with 889 for last year. The income of the Society was 28,000 marks, and the expenses 23,000, and the total assets of the Society amount to 90,000 marks.

Fibromata of Uterus and Carcinoma of the Peritoneum.

At a recent meeting of the Berlin Medical Society, H. Pech showed these preparations taken from a woman, æt. 46, who had been married three years and had suffered from profuse hæmorrhage for 2½ years. Her troubles had gradually increased, there were also violent pain, swelling of the abdomen and dyspnœa. On examination there was found to be extreme cyanosis, bilateral dulness in the pleuræ, œdema of the lower extremities. The abdomen was much distended and protuberant. Tumours the size of the first were observed on both sides, the uterus very much enlarged. On opening the peritoneum eight litres of yellow ascitic fluid were removed; nodulated tumours the size of the first came into view, enclosed in omentum. The uterus was removed in several pieces and the tumour mass in the posterior part of Douglas's pouch was then removed. Old nodulated tumours the size of the fist and of brain-like consistence had a pedicle 5 ctm. in length, consisting of omental tissue in which were embedded smaller tumours. The other tumours were composed of multiple fibroids of the uterus. No degeneration could be discovered.

Prof. Virchow said the tumours of the uterus had the character of simple myomata, the uterus, therefore, had participated in the development of the peritoneal tumours. These showed a cancerous structure, the formation of tubular alveoli with very thick cylindrical epithelium. There was nowhere any indication of a connection with the uterine myoma. He considered it very probable, however, that a primary tumour existed somewhere from which infection of the abdominal cavity had taken place, and it was most probably a dissemination from a part of the digestive tract.

The Staining of Living Cells.

Prof. Ehrich at the same meeting said for a number of years he had been attempting to decide certain biological therapeutic medicinal questions by the introduction of colouring material into the bodies of animals. In the course of his investigation he propounded the question which of all colouring material had the greatest affinity to the living animal. The answer was very simple. On experiments with tadpoles he found that *neutral red* was the best suited for staining purposes, a material that had not hitherto been used in microscopic work but which could be obtained from Grubler. If the colour was diluted and an alkali added a fuchsin colour was produced. From the manner of staining it could be seen whether an animal tissue was alkaline, weakly alkaline or acid. If, for instance, a tadpole was made to swim in a weak solution of neutral red (1-2,300,000); it was astonishing how it absorbed the colouring material. It became red in a quarter of an hour. If they were kept in the fluid a longer time all the tissue of the body, the brain, &c., became perfectly red. The speaker knew of no material so suited for staining living cells as neutral red. Such colouring material must, therefore, be possessed of two properties. 1st. It must be able to penetrate the covering membranes of the living tissues. 2nd. There must be something in the cells that has an active attraction for the staining material. Were these substances in solution or morphitic? A glance through the microscope showed a number of intensive red cells, which, in many respects, corresponded to the cell granules.

The method of colouring had sources of error, however, in two directions—(1) there was the possibility that the apparent granules were only deposits of colouring matter in the cells; (2) by lengthened experiment the nuclei degenerated and became larger. From these considerations sprang the following practical conclusions:—(1) the staining should be produced as quickly as possible; (2) it should be done with the smallest possible material; and (3) as a "control," small pieces of the tissue should be stained in the solution after its death.

If all three factors agree, it might be assumed with certainty that profound nuclei had undergone a vital staining. In the lungs there were certain cells filled with red coarse granules; these were the true phagocytes of the lungs. The extent of staining of nuclei was very great. He had stained both in the higher and lower animals, and in plants. By careful manipulation the colour in the living cells could be varied. Every cell had had its specific nucleus as regarded staining. In a solution used by him there was a little methylene blue from a previous experiment. After the staining the smooth muscular fibres showed the nuclei coloured blue, whilst all the other tissues were red. He was convinced that by the aid of such experiments conclusions on important functions of the living cell granules could be arrived at.

Austria.

[From our own Correspondent.]

Vienna, Jan. 26th.

Osteomalacia and Chloroform.

At the last meeting of the Gesellschaft der *Aerzte* Latzka showed a patient who had quite recovered from this malady after chloroform narcosis. At the present time he said there were two theories ennunciated by Petroni that might be cited as the proximate origin of the disease, viz., the micro-organism or nitrification theory; the effect of castration and Porro operation, which properly depended upon chloroform narcosis. Latzka said that he had observed a marked change in osteomalacia for a few weeks after the application of chloroform, which frequently proved to be temporary. This led him to question the theories more accurately, and in his investigations, according to the proofs of Petroni, who maintained that nitrates were constantly in the urine of the osteomalacia, he failed to satisfy himself that any constant relation existed between the nitrites and the disease. Indeed, three of the cases carefully followed failed entirely in this particular out of seven ; two of the same number presented an occasional testimony after the urine had stood for some time, the remainder very rarely. In the fresh urine nitrites could never positively be proved present. In this, he pointed out, he was not alone, as Karplus had obtained similar results. He considered the nitrification hypothesis of Pretroni to be unsupported from the present proofs.

With regard to the second hypothesis, he brought forward the history of ten cases which had fallen under his own observation ; one of these was a male ; six were puerperal osteomalacia, the other three were non-puerperal. In these ten cases his treatment was simply anæsthesia by chloroform, and of the ten only one remained unaffected, other two were but slightly improved, while the remaining seven were decidedly much better, but unhappily the recovery was of a temporary character. Only one of these cases which he showed had retained any lasting effect. This case had been treated with chloroform seven months ago ; the subjective and objective pains had all disappeared ; the former elastic pelvis is now solid, and the patient considers herself at the present perfectly well.

A second of this number is greatly improved, which possesses some interest from the former treatment under Schauta, who had operated four months previously for double-sided salpingitis with ether, but without any influence on the osteomalacia or relief to the patient. Immediately after the chloroform narcosis four months later the pain was relieved, the luxated joints became firmer, and the patient soon became so much restored that she could move about. As stated above, these brilliant results were but temporary. On this account he attributes many of the successes in castration and Porro's operation to the chloroform and not to the operation itself, although he admits these operations have cut off the function of generation and prevented the return of the disease. In this manner he reasons on the cause of return of many successfully treated cases of osteomalacia with phosphorus whereon the first pregnancy excites the disease. In the chloroform treatment he considers the disease checked, but on recommencement of the menses the disease is excited. From the results obtained he is inclined to believe that some modification of chloroform narcosis may be successfully pursued in the treatment of osteomalacia.

Minimal Fees in Moravia.

The Town Council of Wischau have decided on the fees to medical men for the current year. The honorarium for a single consultation is 50 kreuzers, equal 9d. For a visit to one or more of a family in same house, 1 florin ; if more visits in same place, 70 kreuzers. For a night visit under same conditions, 1½ florin. For a consultation with two medical men, 5 florins ; any other visits by same consultants, 1 florin. If beyond 10 kilometres, 3 florins ; 20 kilometres, 5 florins ; 30 kilometres, 7 florins ; medical certificates, 2 florins ; *visum repertum*, 2 to 5 florins.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Laparotomy.—Satisfactory Conditions after Nephroraphy.—Mr. Bland Sutton opened the abdomen by an incision in the right linea semilunaris of a woman on whom some time previously he had performed the operation of nephroraphy. The present operation was undertaken on account of some of the symptoms returning. Originally there had been pain in both loins, especially in the right, intractable vomiting with intervals, in fact, symptoms of renal colic ; there was, however, at first, an idea of uterine or ovarian trouble, but as pressure on the right kidney caused the vomiting, and as pus was found in the urine it was thought the trouble might be hyo- or pyonephrosis. On very careful examination the case was eventually diagnosed as one of movable kidney for which the operation of nephroraphy was performed ; the surgeon found a very mobile kidney which he anchored in the loin. The result was that the vomiting pain disappeared. On examination just before the present operation a tumour could be felt in the right loin, pressure on which reproduced the former symptoms (the patient being very thin the palpation was easy). The question was now, Mr. Sutton remarked, if it was a distended gall-bladder or the kidney become movable again. Laparotomy and careful and complete examination by the hand in the abdomen proved an enlarged kidney and a slightly distended gall-bladder, this last as Mr. Sutton pointed out, being very natural as the patient had been kept fasting before the operation. The kidney itself was perfectly immovable, therefore the anchoring in the first operation had been quite successful. Mr. Sutton carefully examined the other abdominal organs whilst his hand was in the abdomen and found them healthy ; there was no ulcer of the stomach, therefore he said he was relieved of all anxiety, and opening the abdomen for the second time had removed any prospect of another operation being required in the future.

Epithelioma of a Lupus Scar.—Mr. Bland Sutton operated on a man, æt. 40, affected with a large epithelioma-like ulcer on the wrist. The patient had suffered from lupus of the hand for a period of fifteen years ; the greater portion of the back of the hand was covered by an extensive scar. At the upper part of the scar, situated over the junction of the radius and ulna, there was an ulcer as large as a crown piece with raised, indurated, and everted edges. This ulcer had been slowly growing for sixteen weeks. The epitrochlear lymph gland was enlarged and indurated. Mr. Sutton said that it was an established fact that lupus scars, like the scars of burns were liable to be attacked by epithelioma, but he pointed out that all ulcers at the margins of scars with raised and everted edges were not epitheliomata. Indeed, *no scar should be classed as a scar epithelioma unless the diagnosis was confirmed by a careful histological examination.* Therefore, instead of amputating the arm, he preferred to freely excise the ulcer, and then fill up the wide gap by the transference of a piece of skin from the man's thigh. This was carried out. After excising the ulcer all oozing was checked by sponges wrung out of very hot water ; the skin graft, measuring 5 by 3 cm., was applied and maintained in position by a few very delicate sutures, and carefully adjusted pressure from lint soaked in olive oil and absorbent cotton wool, fixed by soft bandages. The limb was then placed on a splint ; the epitrochlear gland was excised. Mr. Sutton remarked that the excised ulcer would be submitted to reagents and carefully examined. If it turned out to be an epithelioma, and should the disease return, then it might be necessary to amputate the arm.

UNIVERSITY COLLEGE HOSPITAL.

Hip Disease in the Adult.—Chronic Pyæmia.—Mr. Berrka said the case under consideration was a most unsatisfactory one; the man, æt. about 30, had entered the hospital last summer suffering from a large abscess over the chest wall; this had been opened, scraped, &c., but it was evident the patient had been the subject of septic poisoning, as, although he got better, he developed swellings in various joints, which, however, disappeared, excepting in the hip, where the pain and swelling lingered; he was sent away to a country infirmary, but had come back with the pain and swelling of the hip increased. Mr. Barker pointed out that the septic influence had always been subacute, as there were no sinuses, &c. He said he hoped he should not have to excise, as the operation was most unfavourable in the adult, it being very difficult too after the operation to adapt a splint which was convenient and comfortable. The incision was made just under Poupart's ligament, and at its outer fourth about half-an-inch below the anterior superior spine, this being the most likely place the operator stated to find the pus, and also the most convenient to get at the joint; the sartorius was pulled inwards with a retractor, and the tensor vaginæ femoris seen on the outside. The disease was found to involve the acetabulum and upper part of the head, and probably other parts, such as extension up the psoas bursa, but the patient being an adult, Mr. Barker only took away as much diseased bone as possible with a hollow flushing gauge with the hope of getting ankylosis and cure without doing any more. The wound after having been thoroughly dried was sewn up, no drainage being employed, and the limb put up on a Thomas's splint.

RICHMOND HOSPITAL, DUBLIN.

Removal of Adenoids.—Advantage of Rose's position.—Mr. Robert H. Woods, operated on a girl, æt. 19, for the removal of post-nasal adenoids. The growths had been causing nasal obstruction for some months. Gottstein's ring knife was the instrument used. The operation was conducted with the patient in the position advocated by Professor E. Rose of Berlin, the head hanging over the end of the table. Chloroform was the anæsthetic, and the operator expressed himself as having confidence in its safety in such cases if Rose's position were adopted. He believed that the fatalities lately chronicled from operation with the patient's head raised, and attributed to the anæsthetic, ought rather to be ascribed to the faulty position, the elevation of the head inviting syncope.

◆

The New Fever Hospital at Lewisham.

The Metropolitan Asylums Board appears to intend making up for lost time at their new fever hospital, which is to be erected at Hither Green, Lewisham. It is estimated that the building itself will cost £100,000 or thereabouts, to say nothing of the £22,500 paid for the site. In return for this outlay there will be accommodation for 500 patients. Of the total number of beds 36 will be set apart for isolation purposes, 112 for diphtheria and enteric fever cases, while the remaining 352 will be devoted to scarlet fever patients. It seems curious, by the way, that the Board should not be called upon to make provision for so common and infectious a complaint as measles, which is hardly less fatal in its results than those included in the foregoing list.

Competition for Medical Appointments.

The evils of competition are appearing even in the close ranks of the medical profession. The Merionethshire County Council are advertising for a medical officer of health for the county, at the munificent "salary not exceeding £10 per annum." Glamorganshire doctors had better apply at once, as applications have to be sent in before the 24th prox. The successful candidate may send a case of champagne to this office for the intimation.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 31, 1894.

THE UPWARD SPREAD OF SCHOOL OPHTHALMIA.

In a very carefully considered paper read before the Ophthalmological Society last week Mr. Jonathan Hutchinson called attention to a danger which is little less than national. The lesson which he so eloquently propounded conveys moreover a great moral principle—the principle that the persistent neglect of the poorer members of a great community is its own Nemesis. His subject was the recent spread of what we may, for our present purpose, term "workhouse ophthalmia" among the children of our higher middle-class schools throughout the length and breadth of the land. The disease alluded to, which Mr. Hutchinson elsewhere designates as "granular-lid ophthalmia," is a malady which had doubtless existed for years in our workhouse schools before its existence was for the first time officially recognised in Sir, then Mr., Bowman's Report in 1858. Even then it was lightly regarded, so much so that in 1866, when Mr. Hutchinson himself had to report on an outbreak of ophthalmia at the Brentwood Workhouse Schools, he did not recognise the gravity of the affection, though he then and there laid it down as an axiom that the spread of the disease was due to contagion and to contagion only. That indeed is the most important feature from a public point of view of a disease which is still spoiling the sight and disfiguring the features of hundreds of these poor children annually, simply because, from motives of ill-judged economy, guardians have hesitated, and still hesitate, to adopt the only measures which would stay the march of the malady. Now, however, Mr. Hutchinson has sounded the tocsin. He formally notifies his fellow-ophthalmologists, and through them the inhabitants of this country, that the punishment of the middle classes for their persistent neglect of pauper children suffering from ophthalmia in the past, is within measurable distance of accomplishment. Owing to the apathy of some local authorities and the ignorance of others, workhouse ophthalmia has been allowed to take a strong hold on our populations. Until quite recently, however, the disease distinctly justified the appellation of "workhouse" ophthalmia, for it was never met with in schools or establishments frequented by children of the better classes. Seeing that the disease, as described by Mr. Hutchinson, is essentially a contagious disease, a disease, moreover, which is practically uninfluenced by hygienic conditions except in so far as these favour direct infection, it is obvious that it could not remain indefinitely a disease restricted to any particular class of society. From the workhouse it has spread to the mansion, and the neglected workhouse "brat" has the satisfaction of seeing the indifference of one generation of Poor-law administrators visited upon their own children. Lest we should be accused of exaggeration, let us quote Mr. Hutchinson's very words: "Unless proper precautions are taken at once this form of ophthalmia will shortly become an appanage of our middle-class schools, just as it has long been of schools for paupers. From schools it will spread to private families, and unless something in our race peculiarities protects us, bad cases of trachoma may become as common with us as they have long been in France and in Ireland." We have only to reflect for an instant what this means to appreciate the importance and the gravity of the danger thus signalled. Once established, granular lids entail painful and often-repeated measures of treatment; they incapacitate the sufferer to a great extent for most of the pleasures and the duties of life. Those who suffer from them are, for years together, unable to read, and they are, as if to complete their misfortune, compelled to live in a state of semi-isolation. From one or two reports which have appeared in the daily press during the past week we are enabled to form some idea of the prevalence of this affection in schools of a class hitherto exempt therefrom, and it is indeed extremely probable, as Mr. Hutchinson suggests, that were a skilled inspector to visit our middle-class schools the actual state of things as regards the extent of the mischief would be found to exceed the most gloomy anticipations. We publish elsewhere a full abstract of this highly important paper, and under the appropriate heading will be found a synopsis of the discussion that followed, as far as it has at present gone. It is the duty of the medical profession to use their influence at once to render the public cognisant of the danger which menaces them in the persons of their children, and to perfect their own knowledge of a disease which offers peculiar difficulties of diagnosis and treatment. The lay press will not fail to inculcate this practical lesson in medical socialism, and it ought not to be difficult to arouse a wave of public opinion which will suffice to ensure the necessary precautionary measures being promptly carried out. Nothing short of this, we are assured, will protect us against the inevitable spread of a disabling and disfiguring disease. Pressure must be brought to bear on Poor-law authorities everywhere to provide for the isolation of children thus affected, and none should be permitted to leave until they have ceased to be capable of spreading the infection. In all middle-class schools a special room or special rooms should be set apart in readiness for the emergency, and in order to ensure this precaution being adopted "granular-lid ophthalmia" might well be made a notifiable disease.

THE INCREASE OF LUNACY IN THE WEST RIDING.

We have before us a full report of the finding of a sub-committee of the General Asylums Committee on this subject. The following are some of the salient features of the report. There is a decided increase of lunacy in the West Riding, an average yearly increase of 82½. "If the ratio of lunatics to total population were to remain stationary, an average increase of about 50 lunatics would take place, but there seems to be a constant small growth in the proportion of the insane to the sane population, and if, as is not improbable, this fact is in part accounted for by the treatment which now preserves the life of the insane for a longer period than was formerly the case, the increase must necessarily be maintained, unless the causes leading to insanity can be modified, or the number of absolute cases increased." There can be no question that here is the gist of the matter. Whether it be that the average duration of life of the insane has been relatively increased more than that of the sane we have no data beside us to determine. Undoubtedly, however, the hygienic conditions, the dietetic and general treatment of asylums have much improved of late years. The result seems to be that we are prolonging the duration of chronic insanity by prolonging life, that even general paralysis, the most fatal of all forms of insanity, pursues a slower course and has a longer and easier downgrade. But the proportion of cures is not with any certainty increasing, and here is the *crux* of the whole question. A science which prolongs life, but does not cure, according to Malthusian ideas, does more harm than good. If we have any regard for our common humanity we can scarcely endorse this belief. The sub-committee were directed to consider whether there is any probability of the increase in lunacy being arrested by social or other causes which may now be in operation, but they report that there does not appear to be any tangible ground upon which a hope can be reasonably based. An examination of the lunacy figures of densely populated unions in the West Riding gives results widely different from each other. Taking for example the Hunslet and Leeds Unions, both densely populated, and being almost wholly within the county borough of Leeds, it will be found that Leeds Union has 22 lunatics per 10,000 inhabitants, whereas Hunslet has 10·5. The sub-committee very properly refuse to accept these figures as representing rigid fact, and they ask whether there may not be differences in the manner of administering the law which in any degree accounts for so remarkable a disproportion as appears. They also suggest that persons in Bradford and Sheffield Workhouses may be treated as lunatics who would not be so classified at Dewsbury and Halifax. At the two former workhouses there is accommodation for the insane, at the two latter there is no sufficient accommodation for lunatics. The sub-committee suggests, and we think they are right, that the want of accommodation limits certification and registration of lunacy. This fact we laid stress on some months ago, when commenting on Dr. Hack Tuke's discussion of this subject at the Newcastle meeting of the British Medical Association. We speak from personal acquaintance with a large district which has had limited accommodation for years, and we are satisfied that as soon as new asylums are built the ratio of lunacy to the sane population will increase. There have been Royal Commissions for less worthy purposes than to investigate this single alarming question—serious beyond the limits of the West Riding—the steady increase of lunacy throughout the Kingdom.

◆

DUBLIN SANITATION.

There is probably no town in the kingdom or elsewhere in which the "policy of sewage" is so constantly to the front as in Dublin, and at the present moment the sanitary fever is in a state of great exacerbation in consequence of a recent wave of typhoid which has passed over the city. To the tourist or other superficial observer it is manifest that Dublin is dirtier than other cities, inasmuch as it is bisected by a blatant main sewer, which goes under the name of Anna Liffey. To the closer observer the condition of the tenement houses in which the very poor reside is a horrible revelation; while to the sanitarian the unremitting presence of typhoid, week on week off, presents proof that there is something radically wrong. Under these circumstances contending parties are waging war to vindicate their own opinions as to the cause of the acknowledged insalubrity. First there are the Main-drainageites, who want to spend half or three quarters of a million of money upon intercepting sewers to prevent the abominations from emptying themselves into Anna Liffey. This party may be disposed of by the statement that the proposed main drainage will cost an immense sum, and will, when completed, be rather cosmetic than curative—rather ornamental than useful. It will mitigate the ocular and olfactory atrocities which the aforesaid open main sewer presents to the beholders, and, if money were plentiful, it might be well worth while to outlay it for this purpose, but there is no reason to suppose that the purification of Anna Liffey would in any great degree alleviate the death risks of the citizens. On the contrary, so far as the evidence goes, it rather appears that the unsavoury river is, as the open street sewers of the Continent are, useful as a space available for the innocuous decomposition of effluvia, which, if "cribbed, cabinned, and confined," might be much more dangerous. The second corps in the army of sanitary combatants are the Subsoilites. These are a combination of excessively enthusiastic sanitarians, who have got it into their heads that all the evils of Dublin arise from the saturation of the subsoil by excessive water, more or less impregnated with sewer poison, and they are enthusiastically assisted by sanitary engineers and plumbers whose business it is to work up sanitation. This party holds that the beginning of evils was the introduction of the Vartry water supply into the city and the consequent shutting-up of pump-wells, and that that evil has been aggravated by the introduction of the water-closet system by the Corporation. In fact, they ask us to believe that the only two acts of our civic representatives for which we have been accustomed to thank Heaven are those which have destroyed the salubrity of the city, and they want the Corporation to cure these Heaven-sent conditions by reconstructing the whole of the domestic sewerage of the city by the construction of a new system of subsoil drainage. There are a few reasons against their propositions which we may mention, but cannot give space to discuss. *Imprimis*, there is nothing but the most flimsy evidence that the subsoil of Dublin is, in fact, waterlogged. Second, there is very little proof that, if it were, the waterlogging would be likely to disseminate typhoid. Third, it is questionable whether the rooting up of sewers and streets for the purpose of this subsoil drainage would not be much more dangerous to the citizens than the existing state of things. Fourth, it is very doubtful that the excavation of subsoil throughout the city would effect more than it did at the Royal Barracks, where it proved a total failure. Fifth, that it is questioned by the highest authorities that waterlogging of the subsoil has anything to do with typhoid. Lastly, that the expense, which a sanitary enthusiast puts at the moderate sum of £480,000, added to the appalling loss of business and comfort arising from the ripping up of every street in Dublin in as many places as there are houses, would be very dearly bought even if it resulted in the extirpation of typhoid from the City. It goes without saying that all traders interested in sewer works in the Corporation and outside of it are brimming over with philanthropic anxiety for the health of the people, in which we sympathise with them, though we ask that some little interval may be allowed for calm inquiry before these undertakings are entered upon.

◆

Notes on Current Topics.

The Sixpenny Dispensaries and Vaccination.

The "Sixpenny Dispensary" purveyors of the art and science of medicine, surgery, and midwifery always make a point of announcing in the most conspicuous fashion possible that they are prepared to undertake vaccination. Doubtless they regard everything which brings "grist to the mill" in the shape of a patient as a legitimate part of their enterprise, and with this object in view it would appear that many of them have adopted a special method of attracting patients for vaccination, which is disgracefully subversive of the principles of honourable professional practice. At a recent meeting of the Leeds Board of Guardians a communication was read from the King's Norton Union asking the Board to support the guardians of that Union in the action they were taking with reference to the Vaccination Act, and a copy of memorial was forwarded which was intended for presentation to the Local Government Board. The memorial stated that for a considerable time past the public vaccinators in the Leeds Union had found that the number of children presented to them for gratuitous vaccination was yearly decreasing, owing to the fact that the poorer classes were taking their children for vaccination to the sixpenny dispensary practitioners. These practitioners only made one puncture on these grounds, and the suggestion was put forward that the Local Government Board should take steps to make it compulsory on every parent to have his child vaccinated with at least four vesicles, and to compel every practitioner to comply with this regulation, and at the same time to state on the certificate of vaccination the number of vesicles he had made. The guardians unanimously agreed to forward the memorial to the Local Government Board, and we fully endorse their action. An overwhelming mass of facts has been collected showing that the number of marks that are produced in vaccination are directly related to the degree of immunity conferred.

"Truth" and the "Medical Press."

The remarks contained in our issue of the 17th inst. anent the undesirable persistency with which our contemporary continues to advertise certain medical specialists seem to have aroused the ire of its genial editor on the ground, apparently, that similar prominence is given to the names of particular doctors in the columns of the medical journals. It is passing strange that so perspicacious a journalist as the editor in question should not have appreciated the difference that exists between publicity in journals written for and by medical men and publicity in the lay press. We are apparently better informed of what appears in the columns of *Truth* than its editor is of what is published in our pages. This is to be regretted, because the editor of *Truth* might from time to time derive information and advice as good in its way as that which not long since he vouchsafed to the editor of the *Westminster Gazette*—and equally unsolicited. We have no wish to dictate to our contemporary in this or any other matter beyond calling his attention to the fact that such practices are exceedingly distasteful to members of the profession. We are not sanguine enough to suppose that he will apologise to us for his misconduct and promise amendment, and we are satisfied for the time being with having entered a public protest against a practice which is at variance with our ideas of what is just and becoming.

Medical Competition in Jamaica.

Complaints are frequently made in this country of the prescribing qualities of chemists, but the competition which medical men in Jamaica have to submit to with chemists and clergymen appears to be astounding. A medical man writing to a Canadian contemporary asserts that many chemists in Jamaica openly practise medicine, that is to say, they not only prescribe, but actually visit the patients at their homes. In one instance, he knew of a chemist who drove a distance of four miles in order to see a sick person, and for the visit so made a guinea fee was tendered. Then, a few miles from his house, a clergyman is in active practice as a medical man. This state of things is certainly deplorable, and as long as the law remains as it is the evil will continue. This medical man asks, "Would it be possible to bring about inter-colonial legislation in order to prevent this unqualified practice"? Certainly possible, we should imagine, if properly organised steps were taken by the profession in the Colonies concerned. The way to proceed in such a matter would be, of course, first to call meetings in the various localities of all the medical practitioners, and pass resolutions urging an alteration or an amendment of the law. At all events, it is clear that something should be done: the present state of affairs is not far short of a public scandal.

Microbes in Sewer Air.

Is it possible that we have been all wrong in the idea that infective germs are communicated by the ingress of sewer air to our houses? If Mr. Parry Laws, who was employed by the London County Council, is to be believed, this is so. He has presented his official report to the Council with special reference to main drainage, and he declares that the number of micro-organisms in sewer gas is almost always less than in the free air of the locality in which the sewer runs, and that those which are found in sewer air have a closer relation to the germs of the circumambient air than to those of the sewer. These facts, assuming them to be true, do not, of course, affect the necessity for excluding sewer gas from dwellings, but they go to show that, whatever the deleterious effect of sewer gas may be due to, it is not due to microbes, and it corroborates the opinion that zymotics which have their origin in sewer contents are more likely to be disseminated by the direct agency of water and milk than by effluvia escaping into houses. As, however, there can be no question that such effluvia are greatly productive of disease of other sorts, we must look for cause to the presence of some chemical ptomaine of non-microbic character.

The Medical Defence Union now numbers upwards of 3,000 members.

The Future Irish General Practitioner.

We understand that the Irish College of Physicians has had under consideration a proposal to rescind the bye-laws of the College which forbid its Licentiates to engage in the sale of medicines, the intention being to place them on the same level (if they choose to adopt it) as Licentiates of the Scotch Colleges, and break up the monopoly of keeping open shop for the dispensing of prescriptions which is now enjoyed in Ireland by the Apothecaries' Hall and by the Pharmaceutical Society of Ireland. The law of the College on this subject is stated by a former Registrar of the College in its official Register as follows :—

> "Every candidate must, before his admission as a Licentiate, solemnly declare that he will observe the statutes and bye-laws of the College, and, in case of violation of them . . . will submit to censure or expulsion. . . . That he will not engage in any trade in any part of the United Kingdom ; that he will not resort to any unworthy means of obtaining practice or of attracting public notice ; nor use nor permit his name to be used in connection with any secret remedy ; nor compound nor dispense medicines for sale. He may, however, compound or dispense medicines for his own patients. If the candidate for the licence be an apothecary he must, previous to examination, surrender his apothecary's certificate . . . and as long as he remains a Licentiate he cannot be registered as an apothecary."

The declaration now taken by every Licentiate contains the following phrase :—

> "I consent to surrender the diploma received from the College if I shall, after having obtained the licence of the said College, keep open shop for the sale of medicines."

Since this was written the College has instituted the order of Membership. It is, therefore, urged that Licentiates should be relieved of the limitation against sale of medicines, and we are glad to see that the College manifests a wise desire to go with the times and release its diplomates from restrictions which are now out of date. But it ought to be at once understood that, while a repeal of the College bye-laws may relieve its diplomates from collegiate penalties, it cannot give them a title to keep open shop in Ireland or elsewhere for the sale of medicines to others than their own patients. The privileges of the Irish physician may be assimilated to those of the Scotch physician, but such an assimilation will not entitle him to keep open shop for dispensing. It is but a few weeks since we reported the case of a Glasgow medical practitioner who was prosecuted for selling, by the hands of his unqualified assistant, a certain medicine across the counter. He claimed the privilege of his diploma, but it was ruled that registration as a medical practitioner conferred no such privilege, and that, if he desired to keep open shop, he could do so only under the cover of a fully qualified apothecary or pharmaceutist as his assistant, in which case the assistant is the vendor, and not the doctor. Similarly, in Ireland, no person can dispense prescriptions for all comers except a Licentiate of the Apothecaries' Hall or a Member of the Pharmaceutical Society, and the utmost the College of Physicians can do, by repealing its bye-law, is to permit its Licentiates to keep a "surgery" and to charge for medicines supplied to their own patients. It is very right that he shall be free to do this, and we hope that the College will remove all collegiate prohibition to his doing so, but it ought to be understood that such removal will in no way touch the monopoly of general dispensing now held by the Apothecaries' Hall and the Pharmaceutical Societies of either country.

Medical Federation in the Australian Colonies.

An important proposal is now under discussion among the members of the profession in the Australian colonies, namely, the formation of an Australasian Medical Association. A representative meeting was recently held at Melbourne in order to consider the scheme, and a resolution was unanimously agreed to that it was highly desirable that such an association should be organised. In commenting upon this matter, our contemporary, the *Australasian Medical Gazette*, says that the time is ripe for such a movement to be carried into effect, especially if it be conducted on broad lines and with a liberal constitution consistent with upholding the status of the profession. For some years past an association on similar lines has existed in New Zealand, and has, we believe, been a success in every way. The great advantage, of course, of such an association in Australia would be that arising from the formation of branches in the country districts, thus affording country practitioners the opportunities of meeting and discussing the medical and ethical subjects at stated intervals in their own districts. We wish the new association all success, and we trust that it will be warmly supported by the profession, as it is certain that such a federation could not fail in many ways to be of great service to our *confrères* in the Australian colonies.

Corporeal Punishment in Schools.

The general disuse of corporeal punishment is, broadly speaking, one of the greatest reforms ever brought about in our modern educational system. That it should not be universal is a matter for regret in the minds of many humane persons, who hold that in moral measures alone will be found efficient means of punishment, both recriminatory and preventive. At any rate, it is evident that severe physical injury is likely to result from the rough handling of children of tender age. A case in point is reported from St. Helen's in which a coroner's jury found that a schoolboy had died from blood-poisoning. Deceased had suffered from a swollen finger, which was alleged to have followed a blow inflicted by a teacher at the Birchly Roman Catholic School. The coroner advised the jury to return a simple verdict of death from blood-poisoning, as there was no evidence to show how this condition was brought about, owing to the difference of opinion on the part of medical witnesses. At the same time he spoke strongly of the inadvisability of assistant teachers being allowed to punish children in that way. For our own part, we think the power of administering corporeal punishment should be taken entirely out of the hands of school authorities.

The Lay Press on Chloroform Deaths.

THE occurrence of a death under chloroform at the Newcastle-on-Tyne Infirmary has been made the occasion of a remarkable article in the *Daily Leader*, a newspaper issued in that town. The case itself presented no very remarkable features. A labourer, æt. 51, fell down a ship's hold and fractured and otherwise injured his arm. After a few weeks' treatment at hospital the wrist was still stiff, and chloroform was administered with a view of breaking down adhesions in the joint. After this small operation the patient unfortunately did not rally, and died shortly afterwards. In commenting on this case the *Leader* says that important questions are raised in relation to the administration of hospitals. It freely admits that neither want of precaution nor of skill was shown by the two medical men engaged. At the same time it points out that one of the medical men was qualified in April last only, and the other, two years ago. The writer, so far as we can judge from a careful perusal of his article, complains of the system under which young practitioners are entrusted with the discharge of serious medical responsibilities in hospitals. It is hard to imagine, however, how the pressure of work in our large hospitals could be carried on without the services of medical students and recently qualified men. Everyone must sooner or later undertake these serious responsibilities, and there is no safer or better field for their practice than in the wards of a public hospital, where skilled supervision is always at hand. In this Newcastle case one of the medical men was a house physician; both were qualified, and the administrator had given chloroform forty times previously. Just as the writer in the *Leader* at one time launched his first serious article on, let us hope, an appreciative public, so the fledgling doctor must conduct his first labour, administer his first anæsthetic, and set his first broken limb. It is easy to deal in destructive criticism and to point out, as this article does, that the chloroformist to the institution attends for "major operations" only. A little reflection and inquiry would soon convince him that chloroform fatalities occur now and then even in the hands of the most skilled administrators. The writer has managed to stuff his article with a large amount of oblique and sensational innuendo, although he declines to express any specific judgment on the case in question. He would do well to make further inquiries into the working of our voluntary charities before launching forth into this thinly-veiled attack on methods that are plainly outside his experience.

Stoves and their Dangers.

Now that recent high prices have drawn general attention towards the means of economising the consumption of coal, a word as to the dangers of some of those methods may not be altogether out of season. To meet the public demand many inventors have been in the field. For the most part they appear to have taken advantage of two principles, namely, slow combustion and the conservation of radiated heat. These two points are more or less perfectly attained in the ordinary stove, which is constructed so as to throw off a maximum of heat from a minimum of fuel. Thus far, however, the stove cannot be said to have become really domesticated in England, although in other parts of the world, such as cold and temperate Europe and North America, its use is well-nigh universal. Stoves, it need hardly be remarked, are not without their own special drawbacks. For instance, the fact has long been recognised that carbonic acid gas is given off from their cast-iron casing, and also from any accidental obstruction to the "through" draught. Another danger is that of the air of rooms becoming polluted by the products of imperfect combustion. In these and other ways there is little doubt that the public has become saddled with a real additional risk. This is especially the case when a stove is placed in a small and ill-ventilated bedroom. A fire in a good old-fashioned open fire-place—unscientific though it be—carries its products up the chimney and also acts as an exhaust ventilation. How easily the products of combustion may become poisonous when poured out into a limited space has been forcibly illustrated by a recent case in Paris. A medical man, travelling in a cab heated with a foot-warmer, was found to be insensible on reaching his destination. He suffered, indeed, from the effects of carbonic acid poisoning. With that special danger we are not threatened, for, as as a rule, we dispense with the use of foot-warmers in carriages. At the same time the use of stoves, whether for oil, gas, coke, or coal, has increased immensely in England. If such articles are to be admitted to our bedrooms every care should be taken that they are of proper construction, and are carefully fitted upon approved principles by skilful workmen.

The Adulteration of Bread.

IN the Queen's Bench Division last week Mr. Justice Hawkins and Mr. Justice Lawrance delivered judgment in the case of James *v.* Jones. This was an appeal from a decision of the Court of Quarter Sessions of Glamorgan. The appellant was convicted last year of having sold to an Inspector under the Food and Drugs Act a quantity of baking powder containing alum. The decision of their lordships was that the baking powder could not be called an article of food, and directed that the original conviction be quashed. So far as the public is concerned, this appeal has had a most unfortunate termination. Legally, perhaps, alum when mixed with baking powder which is used in the baking of bread cannot be regarded as an adulteration. But if under these circumstances the Food and Drugs Act is unable to meet the difficulty, the authorities might change their venue, and proceed against the baker who used the baking powder in the manufacture of his bread. Presumably the bread so manufactured would show evidence on analysis of the presence of the alum, and if a conviction were secured in this fashion, the alum-made baking powder would not be likely to receive much patronage from the baking fraternity in the future. Indirectly, therefore, the Adulteration Act might still be able to remedy matters in this regard.

White-Lead Substitutes.

THE almost universal use, at any rate in Great Britain, of the poisonous white lead as a pigment has entailed such a series of disastrous results on workmen that it has at length culminated in a Royal Commission of Inquiry. The three chief requirements for a good paint are durability, covering power, and lowness of cost. Of these we find white lead is cheap, and possesses excellent covering power, but it fails in durability, since it quickly blackens when exposed to the products of coal-gas combustion or of a town atmosphere. To replace this convenient but deadly material we know of two substances, namely, oxide of zinc and sulphate of lead, also known as "Freeman's white," or "harmless white lead." Experience shows that the zinc salt is deficient in covering power, but is of remarkable whiteness and durability. As regards the other, Mr. A. P. Laurie, who lately delivered an interesting lecture on this subject before the Society of Arts, reports favourably of the sulphate on all the three points mentioned above as essential. That authority points out that the cost is ultimately lessened, because in grinding the sulphate requires 7lbs. of oil against 9lbs. needed for zinc oxide, and 12lbs. for precipitated white lead. Then there is, of course, the great and enormously important additional fact that the sulphate is non-poisonous. Indeed, its general adoption has hitherto been delayed only by the prejudices of ignorant workmen and the penuriousness of their employers. In this, as in many other matters, the public requires a little enlightenment only, and reform most quickly follow. Let householders be once fully impressed with the fact that sulphate of lead paint is not only harmless, but that it will outlast several coats of white lead pigment, and they will soon insist on being supplied with the cheaper, because the more lasting, article.

A Novel Source of Lead-Poisoning.

THERE seems to be no limit to the number and variety of sources of lead-poisoning. Toxicological annals teem with instances in which the poisonous metal has been introduced into the system by the most unexpected and circuitous paths,—by an excess of perspicuity a case of plumbism was once traced to the common habit of sucking "lead" pencils. In a "Clinical Record," published in our issue for December 27th, Dr. Murrell records a case in which a man employed in an electric light works fell a victim to typical lead colic. We gather from this description that he was employed to beat up and sort the disused leaden plates from accumulators. The plates being coated with a powdery lead salt, this occupation exposed the workmen employed thereat to the usual risks associated with working in lead factories, and several of the hands appear to have developed the characteristic symptoms. A little pressure has been found sufficient in most cases to enable employers to discover a means of obviating these risks to health and life, and this pressure cannot be efficiently applied until and unless the authorities are made cognisant of the incidence of this particular and fatal disease.

The Dermatologists Again!

THE undercurrent of feeling displayed by some dermatologists in London, to which we drew attention in our last issue, has been still further emphasised in some remarks which fell from the ex-President of the Harveian Society during the course of his retiring address, delivered last week. Speaking of the special subject of dermatology, he said: "In our own country, which may be called the birthplace of dermatology, the torch held aloft by William Bateman, Erasmus Wilson, and Tilbury Fox has been handed on to Liveing, Crocker, Colcott Fox, Payne, Thin, Stephen Mackenzie, Pringle, Jamieson, and Brooke. In the hands of such men there need be no fear that the glorious heritage left us by our predecessors will suffer diminution, or that the traditional lustre of English dermatology will be dimmed." It is almost inconceivable that any remarks such as these should have been made and all mention of the name of one of the most distinguished and well-known dermatologists in the world should have been omitted. It is needless to say that we refer to Mr. Jonathan Hutchinson, whose commanding position as a dermatologist has just been signally recognised by his unanimous appointment as President of the International Dermatological Congress to be held in London next year! Doubtless this instance of purposive reticence was not unconnected with the favourable attitude assumed by Mr. Hutchinson towards the formation of the new Dermatological Society. But such tactics as these, however inspired, are more likely to defeat their object than to advance the cause of those who adopt them.

The Coombe Hospital, Dublin.

THE Governors met last week to elect a Matron in place of the lady whose death gave rise to so much comment. Four candidates presented themselves, but the election was adjourned for a month. It is stated in the newspapers that the reason of the postponement was that the whole of the candidates held religious views in which the majority of the Board did not participate, and that they were, therefore, shut out. If this be so we cannot but express regret that the first step taken by the Governors towards reorganisation of the institution which they have allowed to fall into disrepute and inefficiency should make it evident that they have learned nothing from adversity, and are ready to start anew on a system of administration which can only end in disaster. Fortunately for the members of this Board, they are self-elective, and thus can, for the present, set public opinion at defiance, but they ought to recollect that the public are the paymasters, and that Parliament is above them, and that, after all, public opinion is, in the long run, capable of sweeping them out of authority which they have so grievously misused.

WE learn with much satisfaction that Mr. H. G. Croly, of the City of Dublin Hospital, has so far recovered from his prolonged illness that it is expected that, after a brief holiday in Ireland, he will be able to resume his practice and his place in the surgeoncy of the hospital.

The Dublin Shilling Dispensary.

We should like to save the medical proprietors of Dublin shilling dispensaries (to whose speculations we recently referred) the trouble of compiling handbills or otherwise taxing their literary capacity, for which reason we suggest to them the adoption of the following circular which has been largely distributed in Portsmouth by the owners of a similar philanthropic venture :—

WHY PAY DOCTORS' BILLS?

Best Medical Attendance and Medicine, combined with a sum payable at DEATH for the small sum of 2½d. per week.

The following duly qualified gentlemen to choose from :

LOCAL MEDICAL OFFICERS :

[Here insert the names, titles, and personal addresses of the dispensary proprietors.]

For further information call or send postcard to—

G. A. BELL,
3 Commercial Place, Landport.

Apropos of this subject, our attention has been called to an advertisement set forth in the *Dublin Independent* of the 19th inst., from which it appears that another Fellow of the Irish College of Surgeons has achieved the distinguished honour of being appointed Medical Adviser to the Bakers' Trade Union *pro tem.*). The most objectionable part of the announcement is that which recounts the Fellow's hours at home in morning, mid-day, and evening. The development of the shilling advertising system has recently been so rapid in Dublin that it has become pressing for the College to take action.

Hospital Extension in Belfast.

The administrators of the Royal Hospital at Belfast are taking active steps to promote the building of a new hospital on a site at some distance from that now occupied by the hospital, and a successful meeting was held last week to start the movement. The money wanted will be at least £60,000, of which £35,000 will go for the purchase of the premises of the Belfast Charitable Society, but considering that it is said that it will be necessary to pass an Act of Parliament, and that the architects, engineers, and solicitors, not to mention the builders, have to be dealt with afterwards, we rather think that £100,000 would be a reasonable calculation of the expense. But what of that? Belfast is rich, and one of the speakers thinks that he could find forty gentlemen willing and able to put down £1,000 each, so that, if it is worth doing, the rebuilding scheme may be considered as accomplished.

In recently noticing the retirement of Dr. Hawtrey Benson from the Physiciancy of the City of Dublin Hospital, we inadvertently stated that he succeeded his revered father in that position seventeen years ago. This was an error. Dr. Charles Benson resigned the Physiciancy in 1868, and his son was then elected to succeed him, having served as Assistant Physician for two years previously. His total period of service as Hospital Physician was, therefore, twenty-eight years, and not seventeen as stated.

A Tragic Interruption.

At last Friday's meeting of the Clinical Society, Dr Mott showed a man suffering from a curious nervous affection which supervened under peculiarly tragic circumstances. The patient was a professional musician, and, like most of that ilk, was not averse to entertaining his friends. A jovial party had assembled one evening and the host was doing his best to contribute to the general enjoyment at the piano, when he suddenly felt faint and rose to drink a glass of water. He found to his surprise that he was unable to swallow, the fluid returning through the nose. A second and a third attempt were not more successful, and when he endeavoured to explain he discovered that he was also bereft of the power of speech. All this time his friends were uproariously amused at his discomfiture, the gravity of which they failed to appreciate, as well they might. After a time, however, it dawned upon the more intelligent of the party that something serious was the matter, and medical assistance was procured, doubtless much to the relief of the sufferer, who neither desired nor understood the laughter to which his misfortunes had given rise.

The Lepers in Russia.

We see that Miss Marsden is again on the hunt after the Russian lepers. All the newspapers have had a highly eulogistic paragraph about this "philanthropic" person, to the effect that she was again about to visit the lepers' settlement in Russia, and had been provided with an autograph letter from Her Majesty the Queen, in which everyone is asked to render Miss Marsden all the assistance in their power in furtherance of this "noble" woman's self-sacrifice. The only commentary which need be made upon these facts is that "nothing succeeds like success." Miss Marsden has never been famous for hiding her "light under a bushel," and we who have been permitted a view behind the scenes do not share in this quasi-journalistic enthusiasm.

The Use of Cocaine.

The universality of the use of cocaine by surgeons throughout the world makes the official statistics showing the amount of the drug which is supplied by no means uninteresting. In the year 1892 there were imported into London no less than 2,672 pounds of coco leaves; into Hamburg, during the same period, 932 pounds; and New York, 221 pounds. Altogether the total quantity supplied was 3,825 pounds, the value of which was estimated at £16,000. Huanuco, in Peru, is the chief locality from which the coco leaves are obtained. The excess of the produce which reaches the London market is remarkable in comparison with other countries.

The sun's rays have been found to penetrate water to a depth of 553 feet. At this depth the darkness was to all intents and purposes the same as that on a clear but moonless night. Sensitised plates exposed beyond this distance from the surface of the water for a considerable length of time gave no evidence of light action.

The West London Hospital Post-Graduate Course.

The Post-Graduate Course arranged by the staff of the West London Hospital was begun on the 24th inst. with a lecture by the Senior Physician to the Hospital, Dr. Donald Hood, "On the Symptoms of Acute Pneumonia." There was a large attendance, which augurs well for the future success of the enterprise. The course consists of twelve lectures, inclusive of demonstrations, and will be continued on every succeeding Wednesday until April 11th next. The lecture for this day (31st) will be given by Mr. Keetley, the Senior Surgeon to the Hospital, on "Ankyloses and Stiff Joints."

Outbreak of Insanity in a Patient at St. Bartholomew's Hospital.

A regrettable circumstance occurred last week in one of the surgical wards of St. Bartholomew's Hospital. A patient who had undergone a small operation suddenly sprang from his bed and fiercely attacked the sister of the ward. Assistance, however, was promptly forthcoming before much harm was done; nevertheless it was only too plainly manifest that the patient was suffering from delusional insanity, as the result of which it was found necessary to certify him and remove him to an asylum. The patient was a younger brother of a former house surgeon of the hospital, who is now in practice on the South Coast.

Sanitation in Dublin.

Apropos of the sanitation controversy in Dublin, to which we have referred elsewhere, it is worthy of note that the Corporation was occupied last week by a lengthened debate as to what should be done. The discussion was chiefly notable from two statements made by the Chairman of the Public Health Committee, who is himself a sanitary engineer. Referring to the contention of the amateur sanitarians that the excessive death-rate from typhoid is due to waterlogging of the soil, and that the remedy is subsoil drainage, he said:—

> "The results of the subsoil water experiments up to date show that in 1892, when the subsoil water was at its lowest point, typhoid was most prevalent, and when it was highest the typhoid was less marked."

He also said:—

> "Any cross drains laid by the Corporation within the last ten years which were bad should be relaid at the cost of the Corporation, and any bad drains laid by the Corporation more than a few years ago must be laid by the house-owners. *The Corporation laid* 400 *cross drains every year. Within the past ten years they had laid* 4,000 *cross drains, and most of them were bad.*"

A pleasant look-out for the Dublin citizen!

A case of some interest to the profession was decided in the Court of Queen's Bench on Monday last. It was briefly this: Dr. Fenoulhet, of Herne Bay, advised a patient to leave a house because of its insanitary condition: the owner of the house thereupon took an action against him for libel and damage. The hearing occupied the whole day, and ultimately ended in a verdict with costs in favour of Dr. Fenoulhet.

Surgeons and Barbers.

The historic connection between the surgeons and the barbers has its illustration in Dublin at present. The lady-barbers who started last year in London have been introduced into Dublin as a new sensation, and are now plying their trade in a street off Parliament Street. The fact derives professional interest from the statement that the lady-barbers are both patronised and financed by a well-known general practitioner a few doors off from their shop, and from the further circumstance that this medical speculator in "barbarism" is a Vice-President of a London Medico-political Association, and is also a newspaper censor and the most viciously bitter of all the critics of medical propriety in Dublin.

The Death of Dr. Cranstoun Charles.

We have to record with regret the death of Dr. Cranstoun Charles on the morning of the 24th instant. An inquest was held in due course, but was adjourned for a month in order to allow an analysis to be made of the contents of the stomach. According to the medical evidence there were circumstances which pointed to poison having been self-administered. Dr. Charles at the time of his death held the post of Lectureship on Practical Physiology at St. Thomas's Hospital, and it was only as recently as last year that he took the Membership of the Royal College of Physicians, London.

Medical Scholarships for Ladies.

Two scholarships of £100 and £50 respectively have been founded in connection with the Edinburgh School of Medicine for Women by a wealthy lady who is interested in the medical missionary system. The scholarships are tenable only at the School, and the £100 prize will cover the entire expense of medical education thereat and at the hospital.

Poisonings by Carbolic Acid.

From a return recently presented to the House of Commons it appears that in the five years last past no less than 375 lives were sacrificed in England and Wales to this drug, of which 138 are said to have been accidental. Much of this fatality is to be laid at the door of the Privy Council, which persistently refuses to recognise carbolic acid as a poison.

We note that the Sanitary Authority of St. George's, Bristol, has discovered that small-pox has been prevalent in the district for some time, and has grown to serious dimensions because the people have kept it secret, fearing the interposition of the sanitary authority. If the compulsory notification system had not been in force in Bristol it is pretty certain that medical advisers would have been called in by the sufferers long ago, and all necessary precautions would have been taken under their guidance. As it was the infected population kept the doctors out and resorted to chemists, quacks, and unqualified assistants, for the purpose of keeping the existence of the disease secret, and, of course, the infection spread. So much for compulsory notification.

THE death occurred recently of one of the oldest inhabitants of Cardiff, namely, Dr. I. H. Paine. During a large proportion of his life time he paid a great deal of attention to the sanitary condition of the town, and it was largely owing to his exertions that Cardiff has now acquired such an excellent position from a public health point of view. Dr. Paine also held for many years the post of physician to the Cardiff Infirmary, and was chairman to the Board of Guardians, besides being a Justice of the Peace for the Borough. He was born in Canterbury some eighty years ago.

DR. HOWARD W. ACHESON, of Farnham Street, Cavan, has been presented with a purse of sovereigns on his retirement from the appointment of medical officer of the Killenagh Dispensary District.

SIR W. PRIESTLY has been nominated the delegate to represent the Royal College of Physicians, London, at the forthcoming International Medical Congress at Rome.

A SERIOUS outbreak of cholera of a virulent type has occured at Ranipet, in India, and two European ladies have already been numbered among the victims.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

THE MORRISON LECTURES ON INSANITY.—The sketch plan of this year's Morrison Lectures on Insanity has just been published. These lectures, which are biennial, will be delivered this year by Dr J. Batty Tuke, M.D., F.R.C P.Ed., at the Royal College of Physicians, Edinburgh. Dr. Tuke has chosen as his subject: What Lessons as to Treatment can be derived from the Study of the Anatomy, Physiology, and Pathology of the Brain? The syllabus of the lectures indicates that Dr. Tuke intends to demonstrate all the latest discoveries with regard to the histology, normal and pathological, of the brain tissue, including the work of Golgi, Ramon-y-Cajal, and Hodge. There will be five lectures delivered each Wednesday from the 31st January to 28th February, at 5 p.m. It will be remembered that Dr. T. S. Clouston delivered the last course in 1892 on the Neuroses of Development.

EDINBURGH ROYAL INFIRMARY.—The Board of Managers resolved last week by 10 votes to 8 that the meetings be henceforth open to representatives of the press. The Law Committee to whom the question of the validity of members of the staff being at the same time managers reported that legally it was valid but inexpedient. The report was allowed to lie over until next meeting.

THE POWERS OF MEDICAL OFFICERS OF HEALTH.—A question arising out of the action of the Medical Officer of Health of Leith insisting on a small-pox patient being removed to a fever hospital was decided in the Sheriff Court last week. The patient, who was the pursuer, said that she was only induced to consent to go to the public hospital by the threats of the Medical Officer of Health, and claimed expenses for legal and other actions. The action was begun when she was still in the hospital, and she also claimed to be taken back to her own home. Before the proceedings in court commenced, however, she had recovered and been sent home, so that the question was left undecided. The Sheriff dismissed the case without costs to either side, evidently because the pursuer had consented to go to the Fever Hospital herself, and the alleged threats were not sufficiently proved.

INCREASE OF SCARLET FEVER IN GLASGOW.—The Medical Officers of Health for the City report that there are at present 990 cases of infectious diseases existing in Glasgow, an increase of 33 cases—the number of scarlet fever cases having risen from 629 to 652. The number of other infectious cases are as follows:—Typhus fever, 5 cases; enteric fever, 100; puerperal fever, 4; small-pox, 1; erysipelas, 33; measles, 38; whooping-cough, 121; and chicken-pox, 9 cases.

A BONESETTER REWARDED.—A bonesetter in Hawick, George Crosbie by name, was sued some weeks ago in the local Sheriff Court for damages for alleged unskilful treatment of a patient. The jury brought in a verdict in his favour. As the action had entailed on the defendant much trouble and expense, a number of his friends have presented him with a purse of sovereigns. A local manufacturer, who made the presentation, was able from personal experience to speak of the great benefits and advantages to be derived from Mr. Crosbie's treatment. There is no doubt that in many parts of Scotland, and notably in the Border Counties, a bonesetter is looked upon as the equal, if not the superior, of the qualified practitioner in the treatment of sprains and bruises. Nor is this to be wondered at in many instances, because the bonesetter, however little knowledge he may possess, is generally a practical man, and a good, though untrained, masseur. Of course, on occasion they do harm, but frequently the physician might learn from them that a vigorous treatment of a sprain or bruise by passive movement and massage is of more value than a masterly inactivity.

THE BRITISH MEDICAL ASSOCIATION.—A joint meeting of the Edinburgh (Fife and the Lothians), the Stirling, Kinross, and Clackmannan, and the Border Counties Branches of the British Medical Association will be held in Edinburgh on Friday, Feb. 2nd. The programme arranged for the meeting comprises an exhibition of specimens, instruments, and special demonstrations in one of the surgical theatres of the Royal Infirmary, a medical congress with a demonstration of remarkable clinical cases in the large surgical theatre, and a dinner at the Waterloo Hotel in the evening. Professor Annandale, president of the Edinburgh Branch, will be in the chair.

DEATH FROM SWALLOWING FALSE TEETH.—A middle-aged man died on the 26th inst., in the Royal Infirmary from the effects of swallowing a set of false teeth. A medical man was called in to see the patient in his own house, as he was feeling unwell, and on examination the doctor discovered that the patient had accidentally swallowed the upper case of his teeth. His removal was ordered to the Royal Infirmary, where he was taken in in an insensible condition, and where he died.

INADEQUATE VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As bearing upon the comments that appeared in your last week's issue, permit me to remark that I have seen it stated that the protective efficiency of vaccination does not depend on the number of vesicles, and that many medical men appear to act on this assumption in that, in deference to the wishes of parents, they content themselves with vaccinating in one small spot.

It is highly important that this question should be threshed out, and as it seems useless to wait for the final report of the dilatory Commission which has been sitting until everyone is heartily tired of asking when it is likely to be forthcoming, perhaps I may be permitted to deal with it. Apart from the fact that the statistics of the incidence of small-pox among the vaccinated demonstrate an increase of protection in direct proportion to the number of scars, common sense suggests that an eruptive disease with several vesicles must produce a more lasting effect on the organism than one in which the eruption is limited to a single vesicle.

Theoretically, if the one vesicle corresponded in area to the usual four vesicles, the effect would be the same. Not only, however, is this assumption unconfirmed by experience, but it is well known that danger attends the creation of the extensive area of suppuration which this would involve. Vaccinators have been warned not to make their several inoculations so close together that the resulting vesicles will be likely to coalesce, because the risks of septicæmic complications and of generalised varioloid eruption are thereby materially increased.

Under these circumstances any departure from the time-honoured practice of vaccinating in several places ought not to be departed from by those who believe in the protective nature of the operation. When resorted to as a means of evasory compliance with the law such a practice is utterly unworthy of members of an honourable profession. I am, Sir, yours, &c.,

A PUBLIC VACCINATOR.

◆

MIDWIVES AND THEIR DOINGS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think that the following may be taken as a fair example of what will take place much more frequently than at present, when midwives receive recognition in the special form of registration, unless very stringent regulations are framed to the contrary, and most rigorously enforced.

B. B., residing at 14 Myrtle Road, Sheffield, æt. 30, married, 6 children, the last 5 months old, presented herself at the Jessop Hospital on my out-patient day with womb trouble. At her last confinement she was attended by a "certificated midwife from the London hospitals." She was in labour for 48 hours, the waters broke 24 hours before delivery took place; there was loss of blood, which a woman who was with her described as pretty free, throughout the whole labour. The midwife left her in labour, to attend another case whilst labour was proceeding, and said that there was no occasion to call in medical assistance. The patient was confined to bed for two months with a bad attack of phlebitis from the effects of which she is still suffering. Throughout the whole of that time the midwife continued to attend and treat her, prescribing medicine and pills for her. Not regaining her strength, she was at length compelled to present herself at the Hospital. The most ardent advocates for the training and registration of midwives will hardly be prepared to say that this is a satisfactory state of affairs. No doubt they believe that they will prevent women from doing as this woman did; but I fear they will, if successful in their efforts, find that they are mistaken. At all events they must be most cautious in framing their legislation on the subject, and they must see that the machinery by which practices such as this are punished is of the simplest kind, and thoroughly effective. The throwing of more power into the hands of trained midwives is most seriously affecting the prospects of the younger members of the profession, and robs them of the opportunities of gathering that practical experience in this branch of their profession, which is so essential to their success in it in after life. No man can know too much about normal midwifery who is called in to deal with such cases as are abnormal. If the general practice of midwifery is handed over to midwives, such knowledge will become rare, and those who advocate it may rest assured that the work of the midwife will not rest at the attendance upon labour, but, as in the case I have mentioned, will extend to after treatment; and, also, to the treatment of the ailments of children, as has already come under my notice in several cases. I sincerely hope that there will be no attempt to rush legislation through upon this subject, and that no steps will be taken that are not the outcome of the most careful and weightiest consideration. This is not a question upon which the higher lights of the special branch of Gynæcology ought to push their opinions. It is a question for the general practitioner to speak upon, and one to be considered in the light of what the effect will be upon the work and prospects of our younger brethren.

Trusting that you may be able to find space for the above, and thanking you in anticipation,

I am, Sir, yours, &c.,
JOHN W. MARTIN, M.D.,
Hon. Med. Officer, Jessop Hospital for Women, Sheffield.
Claremont Place, Sheffield.
Jan. 22nd, 1894.

HYSTERECTOMY BY THE CLAMP OPERATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is not enough for Mr. Taylor to say that my objections to his proposal are hypothetical when they are based on experience of it? Such a reply shows clearly he has not understood them, but to repeat it is simply this, that nothing save stitching the peritonium on both sides of the stump will keep it tightly round the collar, and this his method does not do.

The question of priority in this or almost any other point is of little or no importance, but if I come across the paper I referred to but could not specify by name I shall let him have it.

I have a clear recollection that the author was of a Roman people, either Italian or Spanish, and I remember the woodcuts clearly showed the purpose and details of the method as anticipating Mr. Taylor's publication. I feel pretty sure the pamphlet is amongst the vast mass of ephemeral literature concerning gynæcology I have accumulated during the last thirty years—most of it hardly worth looking back at.

I am, Sir, yours, &c.,
LAWSON TAIT.
7 The Crescent, Birmingham,
Jan. 23rd, 1894.

THE CONTROL OF HOSPITAL PATIENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with more than ordinary interest your excellent leader on "The Control of Hospital Patients." The questions at issue so ably put are continually presenting themselves to every hospital physician, especially to those in provincial hospitals. It is often a very fine point to decide, not only for an experienced house-surgeon, but also for the physician in charge of the patient. The old arguments, "It is not a prison," "You will be better nursed here," and "You go at your own risk," &c., &c., are often of no avail; and the patient goes out to die, if not on the way, shortly after he reaches home. It is particularly annoying when this occurs in cases of myxœdema, in the second stage of acute nephritis, or of a recovering pneumonia.

Your article will undoubtedly have for its effect the inducement of making one think more seriously, not only on the suicidal aspect of the question, but also on the moral and psychical aspect of it.

I am, Sir, yours, &c.,
WILLIAM DYSON, M.D. Lond.,
Physician to Sheffield General Infirmary.
Jan. 25th, 1894.

MEDICAL MISSIONARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—I scarcely know how I am to take or understand Dr. Rentoul's letter in your number of January 24th—was it meant as a joke or abuse? One of the two it must be. I have not the felicity of knowing Dr. Rentoul. Perhaps if I had I might understand him better, but I do know that he hates to see midwives made more efficient and licensed, and I remember his hostility to them before the British Gynæcological Society when the question was mooted there. Evidently he is very sore on this subject.

First, he speaks of those who have to do with the Zenana Medical College—Examiners and referees than whom I think there are no more honourable men in the profession. He omits all mention of the patrons and patronesses, which include a Royal Duchess and Duke, an Archbishop, and several of the most distinguished bishops, and nobility and clergy, and as President of the Managing Committee, Sir R. Temple. I should have thought these names would prove honourable convictions and intentions. But no, what right have these men to belong to a College whose conduct Dr. Rentoul disapproves!

Secondly, with all this, Dr. Rentoul is clearly a very innocent man in the ways of the world. He voluntarily assumes the position of a *plaintiff* before the profession, "Rentoul *v.* Zenana Medical College." Imagine the simplicity of a plaintiff asking the defendants for information, hoping thereby that they will criminate themselves! Poor man! Is it because he wants a companion in his misery that he calls my apology for the College a very poor affair!

But Dr. Rentoul, I fear, must be under the influence of some nightmare or hypnotising evil spirit. Who asserted that medical practitioners have not "as clean hands and as pure hearts as those who are supposed to be filled wlth some superior influence?" Who said then when a man selected "the practice of medicine as a vocation," the inference follows that he must have dirty hands and an impure heart? I never did say so—*pas si bête, mon ami!* But if it can soothe down Dr. Rentoul's anger I am quite ready to say that Dr. Rentoul has very clean hands, and so far as I know, he may also be "an emblem of purity."

Again, who said that "two years' curriculum turns out a better practitioner, even for niggers, than one of five years?" I am afraid this hypnotising evil spirit has led Dr. Rentoul to read what I never said.

Again, Dr. Rentoul objects to the word "Medical" in the title of the College, the word being included between commas. Does Dr. Rentoul know that the word *medical* does not necessarily mean a *fully* qualified man? Walker defines it as "*physical, relating to the art of healing.*" Thus it may apply to a calling, *medical publisher, medical* instrument maker. Why are *medical* students so-called when they are not qualified? Our ladies are missionaries first, taught medicine up to certain degrees to help them in their calling, and therefore have a right to be called *medical* missionaries.

Then the *diploma* they receive is a dreadfully sore subject with Dr. Rentoul. Now what does *diploma* mean? Does that always imply the right to practise? Walker defines it "*as a letter of writing conferring some privilege.*" A man may have a diploma putting forth his membership of some learned society. The Medico-Chirurgical Society gives one to its Honorary Fellows. It is an honour conferred, but gives them no right to practise medicine or surgery. Many men receive diplomas of merit, who are not even in the profession. The Obstetrical Society of London gives, and has given for years, diplomas to practise midwifery to midwives. But again, to pacify Dr. Rentoul, I append a copy of this fearful document. Our ladies have also to pass the Obstetrical Society's examination besides that of the Zenana Medical College, but it is expressly stated that they can only use their knowledge while missionaries, and for ordinary cases of disease. It is an authentic certificate of ability. It is not sought to be used in England, but is their passport among the heathen.

But I am anxious to give Dr. Rentoul, if he would kindly do so, some further occupation. Only a few months ago a Medical Missionary College, I am told, was opened in London to give its students a training for *under one year.* Also, I am informed that in Scotland there is one which gives 2½ *years' training*, and another in Southern India which exacts 3 years' training. Now I should like Dr. Rentoul to look after these colleges also, and doubtless, with his persevering diligence, he might find several others.

It cannot be denied that our medical missionaries do achieve much good. Dr. A. Neve, Kashmir, says, "I am prepared fully to acknowledge that much good work is being done by some *practically* qualified, though holding no diploma." The Rev. Moir Duncan, M.A. (writing from China as a non-medical missionary): "To witness unmoved suffering unrelieved—to see without sympathy hundreds smitten with notorious common and easily diagnosed diseases, for which he has specific and certain remedies, would be unpityingly to act the part of the Levite."

But now, let me ask a few questions of Dr. Rentoul. Is it true or not that in India *women* can *never* be seen and treated when ill by medical *men?* Secondly, is it true that very few fully qualified medical women, *if any*, and with means at their disposal, go out as medical missionaries? If so, what are we to do with the teeming millions to help them? I will tell Dr. Rentoul. Send poor but willing ladies, it may be not fully qualified but yet knowing a good deal to help these poor creatures, because they are missionaries first, and *medical* afterwards.

Once more, in China shoals of women kill their female children, or throw them into towers built for that purpose outside of cities in the fields, and there they are left to die, and if Dr. Rentoul took a walk in those fields he would hear the piteous wails of these babies in the agony of death. He will hear of women in labour left four days without interference, and then the babes are pulled out piecemeal without skill or knowledge, which generally hastens the mother's death also. Is it not kind and our bounden duty to send these help in the way of trained Zenana Medical College missionaries and midwives? Then look at the poor girls whose feet are put in hard shoes so as to prevent their growth, and yet are so ignorantly attended subsequently that mortification and death very commonly follow! Does this not call for missionaries first, and *medical* afterwards.

Lastly, Dr. Rentoul should take a cruise to Dahomey, and then I would ask him, supposing he was taken a prisoner by the heathen there, would they respect him one bit the more because when contemplating his manly form for a supper, and about to eat him, he should cry out "Oh! don't do it, because I am an M.D., an F.R.C.S., have been registered by the Medical Council, &c"? Would this cry stop their appetites? Why, millions of persons in Africa, indeed in most heathen lands, never heard of such titles. But if one of our compassionate, tender-hearted medical missionaries, who had sweetly tended on sick women and children, and touched the hearts of their monster husbands, was similarly a prisoner, I do not think they would eat her; gratitude would quite tame them.

A woman who imperils her life and health by going to teach the heathen in the Master's name better ways, spiritual and physical, is to my mind much more admirable and grand than those who seek to destroy their unselfish efforts and their holy intentions.

I am, Sir, yours, &c.,
C. H. F. Routh.

Montague Sq., London.

Copy of Diploma of Zenana Medical College, 58 St. George's Road, S.W.:—

We certify that we have examined........................., a student in the Zenana Medical College (who is desirous of combining a knowledge of Medicine with her Missionary work) in the following subjects—Medicine, Disorders of Tropical Climates, Minor and Practical Surgery, including Diseases of the Eye, Midwifery and Diseases of Women and Children, and we find that she possesses such a knowledge of them as will qualify her to render professional aid in ordinary cases of disease.

DENTAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—On November 22nd, you issued a leader on the above subject, setting forth the case of the Dental Advertiser as it then stood. Those of us dentists who were advocating the Petition to the General Medical Council to strike the names off the Dentist's Register of those whom we considered so much disgraced our profession, were full of anxiety for its fate, fearing lest the Council should let "I dare not" wait upon "I would," like so many of our own profession ever have done. The result has shown that my confidence in, and reliance upon, the policy of the Council was justified, and that it is determined to see to the purity of its Register. As you have already, published the resolution moved by Mr. Brudenell Carter, and seconded by Sir Dyce Duckworth, with the discussion upon it, it is unnecessary for me to take up space by quoting it. I will only say that it is intended as a warning note, and will take a legal shape next May Session. This attempt of advertising adventurers to turn a profession into a trade must be seriously grappled with now, and the dentists of Great Britain and Ireland are looking, I hope not in vain, to their medical friends to help them in the matter. We get our diplomas from the same Colleges, and are under the same central authority, and are a part of the medical profession. If we allow this degrading advertising to go on amongst dentists, we feel we are disgracing the whole medical profession, and it is on these grounds we appeal to it to help us all it can by pointing out to patients the true state of the case. Qualified dentists are not, and very soon we hope even Registered dentists will not be allowed to advertise, and a dental advertisement will carry its own condemnation of the advertiser as a man neither qualified nor registered. There is another way in which we are asking our medical friends to help us, and that is by boycotting those advertising and unregistered dentists, by refusing to meet them in consultation or giving anæsthetics for them.

At a full meeting of the Nottingham Medico-Chirurgical Society, held to-night, Jan. 3rd, the following motions, moved by Dr. Tresidder, seconded by Mr. Anderson, F.R.C.S., and supported by myself, were unanimously passed: (1) That this meeting considers it unprofessional for registered medical men to give anæsthetics for unregistered or advertising dentists; (2) that the Notts and Derbyshire Dental Association be asked to furnish every registered medical practitioner in the neighbourhood with a printed list of the local dentists whose names are on the Register, and who do not advertise.

Of course this is a good deal to ask of a medical man—that he will sacrifice a fee of from half a guinea to two guineas occasionally to uphold the dignity of his profession—and perhaps throw those fees into the pocket of some practitioner not so over-nice. But I do not think a doctor will lose in the end, as both patient and dentist will appreciate his care of them and his motive. Besides, even if he did lose a little now and then, we all have to do that to maintain our reputation as professional men. These resolutions have also been passed by the Medical Society of Plymouth, and I hope every medical society in the Kingdom may be induced to follow suit. The whole medical press has helped the movement greatly by publishing letters and commenting on the question. To it we owe great thanks. But, Sir, the game is not ended yet. When the General Medical Council shall have purged our Register from the grosser offenders, they will still advertise, and unqualified and unregistered men will still practise dentistry to the detriment of the public, who are deluded into consulting them.

To meet this contingency we want an Act of Parliament prohibiting any from practising dentistry for gain who are not qualified and registered. This is what the medical profession generally needs also to put down all kinds of quackery. Can we not unite and go together for amendments to the Medical and Dental Acts? It would be a thing worth living for indeed if we could form a society for putting down all forms of medical, surgical, and dental quackery. We legislate against food adulteration, and all kinds of false pretences but medical ones. We leave our friends and neighbours to be preyed upon by the ignorant and the sharper, and we say I will educate myself, and they will die out. But they do not die out; they increase and multiply.

I am, Sir, yours, &c.,
HENRY BLANDY, L.D.S.EDIN.

Special Articles.

THE PROPOSED AMALGAMATION OF THE MEDICAL DEFENCE UNION AND MEDICAL PROTECTION SOCIETY.

[FROM A CORRESPONDENT.]

THE negotiations which were entered into between the London and Counties Medical Protection Society and the Medical Defence Union have come to an end without effecting their object, and unfortunately the amalgamation of these two societies, each of which has the same object in view, is as far off as ever. It is unnecessary to dwell upon the early history of the Medical Defence Union, on the good which it has effected for the profession, on the election of Mr. Lawson Tait as its President, or on the circumstances which lead to Mr. Victor Horsley being selected as Mr. Tait's successor; they are all fresh in our readers' minds. Suffice it only to remark that less than two years ago certain prominent members of the Defence Union, feeling that they were unable any longer to endorse the views and action of their committee, seceded and formed a new society entitled the London and Counties Medical Protection Society, and prominent amongst the seceders was Dr. Mead, of Newmarket, who had been largely instrumental in bringing the Defence Union into existence. Mr. Jonathan Hutchinson was elected President of the new society. In little more than a year and a half from its date of foundation the Protection Society can boast of upwards of a thousand members. It had evidently, therefore, nothing to fear from its older rival. Its Council wisely, however, determined that in such matters there should be no rivalry, and entered into negotiations with the Defence Union for the purpose of effecting a fusion of the two societies. Their views on the point are well described in one of the letters which appeared in our pages:—"Our desire for union was based on the sincere belief that union in the medical profession, as elsewhere, means strength, and that one society is better than two when the objects of both are so nearly identical. The cause which led to the formation of a second society had, we had every reason to hope, ceased to exist." In due course of time two sub-committees, one from each of the two Societies, were appointed, and, as appears from the correspondence, they met and fully discussed matters. Neither committee had power to make any final arrangements for amalgamation, but as far as we can gather from a perusal of the correspondence in question, whilst the committee of the Defence Union reported from time to time to their society the progress of the would-be amalgamation scheme, the committee of the Protection Society did not do so, but waited to learn how far the Medical Defence Union would meet them before laying its proposals before their Committee. The wisdom of these two plans it is not for us to criticise. No doubt each party decided on its own plan of action, and considered it under the circumstances the best that could be followed. But it is difficult to understand how Mr. Victor Horsley, as the President of the Medical Defence Union could send a *résumé* of the proceedings to the medical papers if he clearly grasped the fact which is unequivocally stated by Dr. Bruce Clarke, Dr. Heron, and Dr. Woods in their letter from which we have quoted, viz., that no account of the proposals of the Medical Defence Union had ever been laid before the General Committee of the Medical Protection Society. There is an obvious force in the contention of Mr. Bruce Clarke and his colleagues that no opportunity was ever offered them for laying the proposals before their General Committee. We presume that stated very boldly their meaning is this. It is quite true they would say to the Defence Union that some of your terms were, in our opinion, unreasonable; but we did not know whether our committee would necessarily hold the same opinion as ourselves, and we had no opportunity of asking them before you published your *résumé*. It is certainly due to the members of both Societies that the sub-committee of the Defence Union should clearly state whether they knew, as the Protection Society sub-committee assert, that the committee of the Protection Society had not been formally reported to on the subject of the negotiations. We can hardly believe that Mr. Horsley, if he did know it, would ever have published his now well-known *résumé* of the proceedings. Quite apart, however, from this, it seems clear to us that when two sub-committees meet to discuss any question they constitute, for the time being, a joint committee, and no *résumé* of the proceedings should be published by one party without the consent of all those that composed that committee. If all cannot agree upon a report the dissentients should have the power to pen, should they desire it, a minority report in which their views might find echo. We are surprised that this view has never, at least, been urged by the sub-committee of the Protection Society. But there are other points in this amalgamation failure which require elucidation, and other questions which must be answered before the medical profession will clearly understand how it was that these negotiations came to an untimely end. If we read the matter aright negotiations had proceeded with a reasonable prospect of agreement up to a certain point. The Protection Society, as the smaller concern, was to be asked to wind up, and the members and the good-will of its business, if we may use the expression, were to be transferred to the Defence Union. Having reached this stage it became clear that the Defence Union must agree to accept certain members of the Protection Society, so as to constitute a conjoint committee which should watch over the interests, and carry on the government of the amalgamated Societies. Much discussion evidently took place on the number of new committee-men that should be drafted from the Protection Society to the Defence Union in order to constitute the amalgamated committee, and twenty was the number finally agreed on by the two sub-committees. A further request was, we gather, then made by the Defence Union, viz., that the names of the twenty committee men they were asked to take over should be furnished them. What was the cause of this demand? Mr. Horsley mentions the fact in his *résumé*, but assigns no reason for it. The blank is filled in by Mr. Bruce Clarke, Dr. Heron, and Dr. Woods, for they speak of "the revision of the names of their representatives by the Medical Defence Union," and state that they at once "proposed that the Medical Defence Union should submit its list of councillors to be proposed by the Medical Protection Society. It is further asserted that Dr. Leslie Phillips wrote out this proposal, and we presume gave a copy of it to each of the sub-committees. If this were so, and it has never been denied, what do Dr. Leslie Phillips and Dr. Bateman mean by saying that this "counter-suggestion was utterly meaningless." We must confess that this stage of the proceedings is beyond our ken, and we should like to know why such a demand was ever made, and if it was a reasonable demand for one side to make, why not equally so for the other? On the evidence before us the responsibility for failure clearly does not lie at the door of the Protection Society.

Obituary.

PROFESSOR HIRSCH, BERLIN UNIVERSITY.

This distinguished physician and pathologist, and Professor of Medicine in the University of Berlin, died on Monday last, at the age of 83. During his earlier career as a general practitioner he make extensive researches into the history and geographical distribution of malarial fever, typhoidal maladies, dysentery, aud analogous complaints, and embodied his conclusions in a work of two volumes entitled "Hand-book of Historico-Geographical Pathology," by which Professor Hirsch was regarded as the founder of the study of the geographical distribution of disease, which also secured to him in 1863 the appointment of Professor of Medicine at Berlin University. In the same year he was delegated by the Government to inquire into the outbreak of cerebro-spinal meningitis, then prevalent in an epidemic form in West Prussia. In 1873 he was a member of the German Imperial Cholera Commission, the appointment of which was largely due to his initiative, and in the following year he represented Germany at the International Sanitary Conference of Vienna. For his services on this occasion he received the title of Medical Councillor. In 1879 he went to Astrakhan to study the outbreak of the plague in that province, and compiled an elaborate report on the disease. Among the many works on special subjects written by the deceased was a History of the Epidemics of the Middle Ages, and an important text-book on diseases of the eye.

GEORGE BOLTON, M.R.C.S., L.R.C.P. Edin.,

The Volunteer Service in Sunderland has lost an old and enthusiastic supporter in the death of Dr. Bolton, who held the rank of Surgeon-Major of the Sunderland Artillery Volunteers. He had not been in good health for a protracted period, and for the last few weeks his condition was such as to cause his friends a good deal of anxiety. The immediate cause of death was bronchitis. After becoming qualified Dr. Bolton started practice in Chester-le-Street and whilst there served in the 4th Durham Light Infantry, as an ensign. He ultimately returned to Sunderland, and joined the 1st Durham Artillery Volunteers as gunner on the 17th April, 1867, passing to that rank of acting-surgeon on the 6th July, 1873. He held that rank until 12th May, 1888, when he was promoted to the rank of surgeon, and in December, 1889, he was appointed surgeon-major. On the 28th November, 1892, the deceased was presented with the Volunteer Decoration for service. He acted for a time, and always when there was no resident medical man at the Barracks, as the examiner of recruits, and the hospital doctor. He did a great deal for the Sunderland Volunteer Artillery when the regiment was in a bad way, and he was credited with having revived a drooping corps.

The Medical Benevolent Fund.

At the annual general meeting of subscribers to this Fund, held a few days since at the residence of the Treasurer, Dr. Broadbent, the President, Sir James Paget, Bart., F.R.S., in the chair, the financial statement and the Report of the Committee were submitted to the meeting, from which it appeared that during the past year the relief afforded by the fund had, as is usual, been given in the form of money grants to approved cases and in annuities. The income during the year amounted to £4,748; from investments, £2,073, an increase of £9: donations, £471 14s.; and subscriptions, £1,023 17s., a total of £1,495, as against £1,561 in the previous year. Legacies produced £1,180—£1,000 from the estate of the late Miss M. S. Johnstone and £180 from that of the late Charles Hawksley, M.D. Expenditure.—Grant Department: £1,866 was distributed in grants varying from £5 to £20 amongst 170 applicants, chiefly in instalments, through honorary local secretaries, or through the agency of the Cheque Bank. Annuity Department.—The sum of £2,140 was divided amongst 103 annuitants, 100 being £20 annuitants, 8 at £26, 2 "Dunlop Gift" and "John Morgan." The recipents of annuities are members of the medical profession, or their widows or daughters of more than 60 years of age, and are selected by a special Committee, meeting twice a year to decide which are in the more urgent need of permanent assistance, and in many of cases the annuities they receive are all that stands between them and parish relief. The annuities are £20 each, though eight of them have been increased to £26 a year through a special fund, and the number of annuitants have increased from 51 in 1883, who received £1,062, to 103 in 1893, who received the sum of £2,140. Notwithstanding the large increases in the number of persons receiving annuities, the applications from others in need of immediate relief has been so much in excess of those for many years that the funds available for this purpose derived from donations and annual subscriptions have fallen far short of the needs of the Committee.

Three vacancies occurred upon the Committee, and Drs. George Eastes and J. Lowe were elected to supply them. The resignation of Dr. John Bright was received with regret, and he and Dr. Brett were elected Vice-Presidents of the charity. Votes of thanks to the chairman of committee, auditors, treasurer, and hon. secs., the Medical Press, and Sir James Paget were accorded and suitably acknowledged. The Committee, in drawing attention to the deficiency of funds, mentioned above, would observe that the entire work of the charity is voluntary, only printing and stationery costing anything, collectors' commission excepted. Every penny subscribed is available for the services of the fund, and they would draw the attention of the profession to the work and utility of the charity, and solicit a corresponding increase in subscriptions instead of the falling off the Committee so greatly deplore. Subscriptions and donations should be sent to the treasurer or hon. financial secretary, Dr. Sidney Phillips, 62 Upper Berkeley Street, London, W.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

FIVE CASES OF PSEUDO-HYPERTROPHIC PARALYSIS IN ONE FAMILY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I regret that stress of work prevented the corrected proof of my report of Five Cases of Pseudo-Mypertrophic Paralysis reaching your printer in time to be inserted

May I now state that the woodcut is from a photo of the eldest son, aged 15 years, taken shortly before his death. He had to be supported in this posture for the short period during the taking of the negative. It shows well the general appearance, contractions, and curvatures in an advanced case.

In the table showing the nerve supply of various muscles there are italics "id," which of course should have been "1 D," viz., first dorsal nerve, in the description of the composition of the inner cord of the brachial plexus. I had also intended to refer to the treatment by thymus gland extract, which is now on trial.

I am, Sir, yours, &c.,
J. CHRISTIAN SIMPSON, M.B.

Tunbridge Wells,
Jan. 18th, 1894.

⁂ So soon as our correspondent has completed his experimental treatment with the thymus gland extract we shall be pleased to afford space for further notes.—ED.

Country Practitioner.—We have so far been unable to obtain the information you want. Those to whom we have applied appear never to have heard of the invention; but we shall pursue our inquiries, and hope to be in a position to inform you if such a contrivance exists in our next.

ALL SAINTS' CHILDREN'S HOSPITAL.

Two corresponddnts have asked where this institution exists, as it is not to be found in the Medical Directory. From inquiries made we are enabled to give the following information: It is under the direction, and in fact, part of All Saints' Sisterhood, and is situated at 4 Margaret Street, Cavendish Square, London. It is essentially for chronic cases, such as caries of the spine, joint disease, &c.

Erratum.—In the report of a specimen exhibited at the West London Medico-Chirurgical Society in our issue of the 10th inst., page 87, for "boy's" heart read *dog's* heart.

THE METROPOLITAN MEDICAL PROVIDENT ASSOCIATION.

For the information of correspondents who have written us regarding the whereabouts of this institution, we have, through the courtesy of a private letter from another correspondent, ascertained the following facts: "This Association is situated at 5 Lambs Conduit Street, London, W.C., and is doing very good work, and would be still better if the out patient departments could be reformed and brought under some rational system. Your correspondents should apply to the Secretary for further information."

Meetings of Societies, Lectures, &c.

WEDNESDAY, JANUARY 31ST.

London Post-Graduate Course.—Hospital for Consumption, Brompton, at 4 p.m., Dr. Green: Bronchitis and Emphysema. Royal London Ophthalmic Hospital, Moorfields, at 8 p.m., Mr. A. Q. Silcock: Myopia.—Hospital for Skin Diseases, Blackfriars, at 1 p.m., Dr. Payne: The Treatment of Eczema.

West London Hospital (Hammersmith).—At 5 p.m., Mr. Keetley: Ankyloses and Stiff Joints. (Post-Graduate Course).

THURSDAY, FEBRUARY 1ST.

Harveian Society.—At 8.30 p.m., Dr. W. J. Gow: Eight Cases of Vaginal Hysterectomy for Cancer.—Dr. W. R. Dakin: Modern Methods of Treating Post-partum Hæmorrhage.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street, at 3.30 p.m., Dr. Barlow: Cases in the Wards. National Hospital for Paralysed, Bloomsbury, at 2 p.m., Dr. Buzzard: Cases in the Hospital.—Central London Sick Asylum, Cleveland Street, W. at 5.30 p.m., Mr. Thomas Bryant: Cases in the Wards.

FRIDAY, FEBRUARY 2ND.

West London Medico-Chirurgical Society (West London Hospital).—At 8 p.m., Pathological Specimens:—Dr. Clemow: Perforated Gastric ulcer.—Mr. J. R. Lunn: (1) Case of Appendicitis; (2) Growth of Pancreas ulcerated into Stomach, Fatal Melæna: (3) Perforation of Sigmoid Flexure, Peritonitis and Sudden Death. Papers:—Mr. Alban Doran: The Feeding of Patients after Abdominal Section.—Mr. Lenthal Cheatle: Complications in certain Ear Diseases and their Treatment.

London Post-Graduate Course. — Hospital for Consumption, Brompton, at 4 p.m., Dr. Green: Cases in the Wards.

West Kent Medico-Chirurgical Society.—At 8 p.m., Dr. Bantock: On the Diagnosis of Abdominal Tumours and Intumescence.

SATURDAY, FEBRUARY 3RD.

London Post-Graduate Course.—Bethlem Hospital.—At 11 a.m., Dr. Corner: Stupor, Catalepsy, Katatonia, Dementia.

MONDAY, FEBRUARY, 5TH.

Odontological Society.—The President (Mr. F. Canton) will read his Inaugural Address.—A discussion upon Root Filling will be opened by Mr. H. Baldwin.—Casual Communications by Messrs. F. J. Bennett, Storer Bennett, Hern, and J. F. Colyer.

St. John's Hospital for Skin Diseases.—At 6 p.m., Dr. Morgan Dockrell: The Lichens.

Vacancies.

Alnwick Infirmary.—House Surgeon (unmarried). Salary £120 per annum with furnished apartments, attendance, coal and gas. Applications and testimonials to the Medical and Managing Committees on or before Feb. 16th.

Brighton Throat and Ear Hospital.—Non-Resident House Surgeon Salary £52 per annum. Applications and testimonials to the Sec. on or before Feb. 5th.

City of Dublin Hospital.—Visiting Physician. Applications to the Hon. Sec. Medical Board by Saturday next. (see advert.)

Greenwich Union Infirmary.—Second Assistant Medical Officer (unmarried). Salary £80 per annum, with board, lodging, &c., Applications and testimonials to the Medical Officer on or before Feb. 5th.

Owens College, Manchester.—Professorship of Zoology. Applications to the Registrar on or before April 3rd.

Ramsgate and St. Lawrence Royal Dispensary and Seaman's Infirmary.—Medical Officer (unmarried). Salary £120 per annum, with furnished apartments, gas, firing, and attendance. Applications and testimonials to the Sec. on or before Feb. 6th.

Salford Royal Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications and testimonials to the Institution on or before Feb. 15th.

Whitechapel Union Dispensary.—Assistant Medical Dispenser. Salary £90 per annum, increasing £5 yearly to £100 per annum. Applications to the Clerk to the Guardians on or before Feb. 3rd.

Appointments

Gibbon, W., L.R.C.P. Irel., L.F.P.S. Glasg., *pro tem.*, Acting Superintendent to the Joint Counties Lunatic Asylum, Carmarthen.

Gibson, E. A., M.B., C.M. Glasg., House Surgeon to the Paddington Children's Hospital, London.

Jackson, C., L.R.C.P. Edin., L.F.P.S. Glasg., Medical Officer for the North Sanitary District of the King's Lynn Union.

Maingay, H. B., M.R.C.S., L.R.C.P. Lond., Assistant House Surgeon to the Scarborough Hospital and Dispensary.

North, T., M.B. Dub., B.Ch., Medical Officer for the High Sanitary District of the Longstown Union

O'Sullivan, M. U., L.R.C.P., L.R.C.S. Edin., Honorary Surgeon to the St. Vincent's Hospital, Melbourne, Victoria.

Ramsay, F. W., M.D. Dunelm, M.S., F.R.C.S. Edin., Honorary Surgeon to the Royal Victoria Hospital, Bournemouth.

Robertshaw, W. M., M.B., C.M. Edin., Medical Officer of Health to the Stockbridge Local Board, Yorkshire.

Stephens, W. J., M.R.C.S., L.R.C.P. Lond., Second Assistant Resident Surgeon to the General Dispensary, Nottingham.

Torrance, J., M.B., B.S. Univ. New Zealand, Public Vaccinator for the district of Campbelltown, New Zealand.

Waterhouse, H. F., M.D., C.M. Edin., F.R.C.S. Eng., Surgeon-in-Charge of the Aural Department, Charing Cross Hospital.

Welch, J. B., M.B. Lond., M.R.C.S., Honorary Consulting Physician to the Children's Hospital Birmingham.

Births.

Archer.—Jan. 23rd, at Foregate Street, Chester, the wife of Arthur M. Archer, B.A., M.D., of a son.

Gillett.—Jan. 24th, at Elmhurst, Eastleigh, Hants, the wife of J. F. Gillett, M.B., of a son.

Ruel.—Jan. 15th, at Cromwell House, Kent Road, Southsea, the wife of C. Percival Ruel, L.R.C.P. Lond., M.R.C.S. of a daughter.

Marriages.

Slevin—Dunne.—Jan. 25th, at St. James's, Spanish Place, London, Dr. P. Slevin, of West Drayton, Middlesex, son of Dr. J. Slevin, F.R.C.S., J.P. co. Longford, to Eugénie, daughter of the late Jeremiah Dunne, Esq., J.P., of Dublin.

Wyncoll—Dorman.—Jan. 23rd, at St. Paul's, Cheltenham, J. W. Wyncoll, M.B., C.M. Edin., of Buckfastleigh, South Devon, to Emily Jane Dorman, of Cheltenham.

Deaths.

Clarke.—Jan. 28th, at Abbey House, Kenilworth, suddenly, John Clarke, M.R.C.S., L.S.A., aged 69.

Fisher.—Jan. 24th, at Newcastle-on-Tyne, Alexander Fisher, M.D., Deputy Inspector General R.N. (retired).

Leech.—Jan. 18th, at Broseley, Salop, of apoplexy, Arthur Herbert Leech, M.R.C.S., late of Woolpit, Suffolk, aged 34.

CLIFDEN UNION, CLIFDEN DISPENSARY DISTRICT.—MIDWIFE WANTED.—The Committee of Management of the above Dispensary District will, at their Ordinary Meeting to be held at the Dispensary, Clifden, on the 7th day of FEBRUARY, 1894, at the hour of One o'clock, p.m., receive and consider applications from duly qualified persons (Trained Nurses) for the office of Midwife for the above Dispensary District, at a salary of Twenty-five Pounds per annum. Applications with Testimonials to be lodged with me not later than Twelve o'clock noon on day of election. Candidates to be in attendance.—By Order,
WILLIAM GORHAM, Hon. Sec.
Clifden, Connemara 23rd January, 1894.

Original Communications.

ILLUSTRATIVE CASES OF DISEASE OF THE OVARIES REQUIRING OPERATION.

By SKENE KEITH, M.B., F.R.C.S. Ed.

THE treatment of chronic inflammatory disease of the ovaries and Fallopian tubes varies from the two extremes of doing nothing, and removal of the organs entirely. There are many cases where a middle course is the more satisfactory, and the difficulty is to determine which cases can be cured without a radical operation, and those where the patient cannot hope for a return to health without going through this ordeal. My own conviction is, that in the present state of our knowledge there are some cases, even where the disease has not gone on to suppuration, which can only be cured by a surgical procedure. Our aim ought to be to reduce the number of such as much as possible, and at the same time endeavour to differentiate those where it is only waste of time to try any less heroic means of cure.

One very important question naturally arises, and that is, what is the length of time which usually elapses before the patient is in a perfect state of health after removal of the ovaries and tubes for so-called inflammatory disease? This is most important. I consider that two years, at least, must be allowed to most women to become perfectly well after this operation; and this opinion is based not only on the experience gained with my own operation cases, but also from being consulted by the patients of others after operation had been performed. It may be taken that all patients do not take so long to recover, some on account of greater recuperative power, and others on whom the operation has been performed in an early stage of the disease, or perhaps unnecessarily. Progress after the operation is sometimes extremely slow, indeed, at the end of six months or even a year, it may be, that the patient is not stronger than before, but in the second year progress is much more rapid. It cannot therefore be expected that the treatment of a less radical nature will result in a cure within a few months. Unfortunately, the fact of the slowness of convalescence is not sufficiently brought before the patients, and once they know that an operation will cure them they are apt to grudge the time spent on other treatment, thinking somewhat naturally, that after the operation—the last resort—they will quickly be well. This is an entire mistake, and it will be found that those women who can be cured by means short of removal, will get well more quickly than those who have had to resort to this procedure. Nor is it difficult to understand why this should be; in one case, that of operation, we have first the shock or injury, and secondly, and of greater importance, there is the artificial menopause which is produced. We know that even at its natural time, at the age of forty-five or fifty, there is not infrequently much nervous disturbance at the change of life. When the change is produced artificially, ten, or may be twenty years, before the system is prepared for it, there will be usually a greater disturbance. We cannot alter the fact that between the ages of fifteen and fifty, the generative organs of women play a greatly more important part than they do either before or after those ages. Before the first they are not fully developed; after the second they are functionally inactive. Nature has ordained that for a certain number of years those organs are to be in an active state. If then, we disarrange nature the woman must suffer, at least for a time. One point of great difficulty requires explanation; it is this, that whereas women from whom two ovarian tumours have been removed, suffer comparatively little after operation and recover quickly, though subject to flushings for many years: women, after removal of the ovaries, regain their health much more slowly. This fact may be partly explained in the following way:—those women from whom I have considered it necessary to remove the ovaries for inflammatory diseases have been, more or less, of the neurotic type of women, and I would guard myself against the idea that I mean "nervous women," for all women with disease of the ovaries become, in time, neurotic. What is meant is the nervous type, women in whom the nervous system dominates, and which is, in its turn, often dominated by the organs of generation, when these are diseased. In those women, therefore, the alteration made by the artificial menopause is greater than in the average woman on whom the operation of double ovariotomy may become necessary. In one of my early cases of ovariotomy, I had one case of extremely slow return to health after operation, thus bearing out this idea to a certain extent, as the patient undoubtedly belonged to the type I speak of. Four years ago I had a second case, where, even now, the lady tells me that she often wakes up feeling depressed and unhappy, and this is only since double ovariotomy was performed. Another reason must not be lost sight of; it is that the general health is either not so much broken down before ovariotomy, or the descent from health has been much more rapid than when the ovaries have been removed for chronic inflammatory disease. Still there is something behind, possibly some change in the nervous system, some great lowering of its vitality, due perhaps in the first place, to increased excitability.

Removal of the ovaries must not be performed unnecessarily, but the operation ought not to be delayed after it has become evident that a cure cannot result in any other way. The record of the following cases operated on within a few weeks of each other gives some idea of the length of time which is often allowed to elapse before operation is resorted to, and also of the different conditions which may be found in the pelvis. Mrs. W., æt. 34, no family, began to suffer without any known reason with pain in the back and sides, these pains being aggravated every month. Menstruation was regular.

About three years after the pains first began, an operation was performed in Melbourne, and it was supposed that both ovaries had been removed. This operation appears to have been a formidable one, and the lady was not expected to recover for some days, and was unable to leave the private hospital for three months. A drainage tube was required for ten days. The operation was not a success, for the pains became steadily worse, and in addition there was much nausea. Menstruation was regular as before. A year afterwards Sir Spencer Wells advised a second operation, if improvement did not soon take place. Dr Matthews Duncan was also consulted, but did not think well of the suggestion. In another year's time, every third period became a flooding, and in the intervals the nausea and feeling of ill-health became worse. In addition, there were several very severe attacks of abdominal pain, one of these attacks being relieved by a large rectal injection. The bowels had become much constipated. Nearly five years after the operation the patient came to Europe in the beginning of the year, and while at Lausanne was confined to bed for nine weeks with hæmorrhage. Later, a well-known gynæcologist in Vienna was consulted, and curetting was suggested.

When the lady came to London it was found on examination that the uterus was fairly normal; on the right there was a soft and tender swelling closely connected to the side of the womb; on the left, no swelling could be made out, but the whole of that side was exquisitely tender, both internally and externally. As it seemed to be probable that the first operation had not been a complete one, a second was performed in April. The old scar was cut through, and on drawing up the soft swelling, which had been felt to be attached to the right side of the uterus, it was found to be a knuckle of small intestine joined together by a short thick band of adhesion, and connected to the uterus by a second band as thick as an ordinary cedar pencil. These adhesions were divided between double ligatures. Fully half an inch of the uterine end of the right, and rather more of the left, tube were removed; and the left ovary was discovered, close against the pelvic wall and enclosed in the layers of the broad ligament. A drainage tube was left in for two days. Convalescence was easy, and the lady went to the country at the end of five weeks, and when she sailed for Australia in August, had gained considerably in weight and was almost quite well.

Mrs. O., æt. 35, married fifteen years, four children, had suffered from the birth of her first child. She complained of constant pain in both sides, in the back, and down the legs; she was very thin, said she always felt ill and miserable, and certainly looked wretched. She had been treated by over a dozen doctors; once continuously for fifteen months with pessaries, &c., without obtaining any benefit. Finally she consulted Dr. Currie, of Finsbury, who advised operation and sent her to me. On examination, the uterus was found to be lying backwards, and on both sides a large tender swelling was to be felt.

The operation was performed in May; the left ovary was as large as a turkey's egg; it was partly enclosed in the broad ligament, and partly adherent to the intestine. I ruptured it during removal, the contents being dark, tarry-looking fluid; the right ovary was half the size of the left. Both tubes were enlarged and swollen. The pelvis was slightly washed out and then sponged dry; a drainage tube was not used. Convalescence was easy and in July the husband wrote as follows, "I am sure you will be glad to know that the operation has given her relief and a sense of enjoyment of life not experienced by her for many years previously."

Mrs. H., æt. 37, was sent by Mr. Hawkridge, of Welshpool. She also had not been well since her first child was born twelve years ago; for years she has not been able to dance, ride, nor stand, and has been unable to go out anywhere, chiefly on account of this inability to stand. She was never free from pain, and was more like a skeleton than any woman, not actually confined to bed, I have ever seen. She had been treated in different parts of the world by eighteen doctors, by blisters, glycerine pads, &c., always with benefit, but with a quick relapse as soon as the treatment was discontinued. The pain was chiefly in the right thigh, in both sides, and in the back, aggravated at the periods, and on the slightest exertion. Examination showed that both ovaries were enlarged, the right prolapsed and the tubes hard; and this was found to be the case at the operation in May. The veins were enormously distended. In three months the patient had made considerable progress, and was gaining weight, 6½lb. during the third month.

Miss M., æt. 41, has been a specially interesting case. About five years ago this lady's kidneys became diseased, and she was said to have had on several occasions uræmic convulsions. She kept about and busy, however, till two-and-a-half or three years ago, when she had an attack of pelvic peritonitis; since then there has been a recurrence every four months, and for eighteen months before the operation, she had been confined to bed. Three obstetric physicians, attached to large hospitals declined to operate, and a well-known specialist was of opinion that the condition of the kidneys would prevent surgical interference being successful. Fifteen months before operation, an abscess had discharged through the rectum. In the month of January there was an attack of cystitis.

Examination of the urine showed that the sp. gr. was 1024, that there was but a trace of albumen, at one time there had been one half; and casts, at one time plentiful, were entirely absent. The amount of urea excreted was 315 grains. The uterus was completely retroverted, absolutely fixed, and the contents of the pelvis were very much matted together. The temperature had not been below 99·8 deg. for six months, and the pulse had seldom been counted at less than 100.

The operation was performed in the country, in the beginning of June. Dr. Blaxall gave ether, my brother assisted me, and Dr. Swindale was present. On opening the abdomen all entrance into the pelvis was completely prevented by adherent intestine, which was attached to the peritoneum in front and extended across the abdomen at a level of a couple of inches above the pubes. The adhesions were detached in front over the pubes and bladder, the bowel being separated in every direction until the coils could be got out of the pelvis. The anterior surfaces of the uterus and broad ligaments formed the floor of the pelvis; the tissues below feeling quite solid, and nothing like an ovary or tube could be felt. At this stage the completion of the operation seemed to be hopeless. Assisted, however, by the finger in the vagina I was enabled to dig behind the uterus, and thus reach the end of the right tube; then working along it, tearing vascular adhesions, this tube was freed, and the ovary below got out. The left tube was even more firmly fixed than the other, and it contained some thick, curdy pus. The ovary was situated in a solid mass of adhesion, lying on the pelvic wall. By the time the operation was finished, the uterus did not tend to retrovert, its posterior attachments having been so completely destroyed. A drainage tube was left in. Immediately before the operation the pulse had been 116, after it was over it was 100, and it quickly fell to 80, the slowest it had been for many months. Time of operation 55 minutes; the friends who were "well up" in surgical matters had expected that it would take at least a couple of hours! In some respects it was the most difficult operation of the kind I have ever performed, and one which I could not have completed had I not learned, from previous experience, the great amount of force which can be used in the pelvis, when applied in the proper direction.

Eighteen hours after the operation the patient was vomiting incessantly, and the pulse had risen to 150. One-twelfth of a grain of morphia was given hypodermically, and was quickly followed by the passage of flatus. Within the next four hours the pulse fell 20 beats. On the fourth morning the temperature was 98·8 deg., the lowest it had been since January. The drainage tube was taken out at the end of five days, 12 ounces of bloody serum having been removed.

Within seven weeks the lady was able to get into the garden, the first time in nearly two years. Four months after the operation, she was able to walk about the house, take long drives, and had walked close on 100 yards, and she is now gaining weight steadily; still, she will not be well for a long time.

The Lettsomian Lectures
ON
PERITONITIS. (a)

By FREDERICK TREVES, F.R.C.S.,
Surgeon to and Lecturer on Surgery at the London Hospital; Examiner in Surgery University of Cambridge.

Lecture I.

I have ventured to select peritonitis as the subject of these lectures, not only on account of the fact that the diseased conditions known by that name still occupy a terrible prominence among the causes of death, but because the present time appears to be peculiarly convenient for reviewing the clinical and pathological aspects of this fatal trouble, and for criticising opinions which the custom of years has endued with a spurious appearance of accuracy.

The Nature of Peritonitis.—By peritonitis is understood an inflammation of the peritoneum. From the limited standpoint of morbid anatomy no exception can be taken to this definition, but when it is assumed that the various clinical phenomena which are classed together under the title of "peritonitis" are due, either solely or in the main, to an inflammation of the great serous membrane, then the definition becomes to some extent misleading.

It may almost be said that peritonitis, clinically as well as pathologically, has comparatively little to do with inflammation of the peritoneum, and it would be erroneous to state that the majority of those who die of what is called peritonitis die of a peritoneal inflammation.

In order that this very fundamental matter may be fully discussed it is necessary that two questions should be considered. The first concerns itself with the general nature of inflammation, and the second with the relation peritonitis bears to that process.

(1) The Purpose of Inflammation.

If one may judge from the terms and expressions which are in common use respecting inflammation, and if deductions may be drawn from those ready criticisms of the process which are uttered without fear of scientific cavillings, then inflammation is still the dread thing it was many centuries ago, when phlegmon was a ruthless fetish, and when the antiphlogistic regimen was the only means of propitiation. Inflammation is still referred to as a calamity, as a thing that is violent, as an utter evil, and as an ill wind that can blow no other than ill. It is spoken of as "breaking out," and made comparable with a riot which lays waste a peaceful city. It is often said that the patient "did well until inflammation set in," or that "his progress towards recovery was cut short by a fatal attack of inflammation."

The treatment which should be directed against this evil is commonly assumed to be of the same heroic type as are the drastic measures which may be taken to arrest the progress of fire and pestilence. Inflammation was represented in the literature of the past as the great enemy of mankind, and even in the popular science of the present it retains no little of its satanic disposition.

This view of the inflammatory process needs to be amended, and a very brief survey of some examples of the process should quite justify such amendment. A man, let it be supposed, receives a lacerated wound of the hand in dissecting the body of a patient who has died of puerperal fever. He becomes thereby inoculated at the wounded point with what is practically a culture of pus-producing cocci.

Now, as the human body is an excellent medium for the cultivation of bacteria, the micro-organisms begin forthwith to settle down and multiply. But here steps in the process of inflammation. Under its ægis the cells of the body rise in their millions against the invaders, and there takes place at the point of the outbreak a battle which—if the account of Metchnikoff and others is to be accepted—is without a parallel in the very deadliest warfare imagined by man.

It is by the inflammatory process that the poison is destroyed, and the growth of the parasite is arrested.

But with inflammation a man who is accidentally inoculated with a septic micro-organism becomes at once little more than a test-tube, prepared for the favourable development and culture of the particular coccus or bacterium. In malignant pustule can be well seen the desperate struggle which takes place in the tissues between the invading bacillus and the aroused and active cells of the body. This conflict is a representation of the inflammatory process, and the beneficent purpose of the change is splendidly obvious. But for this inflammation, which has been so much condemned, a human being may be regarded as an organism not far raised above the level of a peculiarly shaped mass of intelligent agar agar.

In a case of tuberculous phthisis it is generally assumed that a destructive inflammation of the lung is the chief cause leading to the patient's death. It is not the inflammation which is to blame but the bacillus which has caused it. How long it would take for the non-resisting lung to become wholly occupied by this particular bacterium it is impossible to say, but it is safe to assert that the inflammation of the lung prolongs the infected man's life, and that his prospects of improvement and recovery depend almost wholly upon it. How many lives and limbs have been saved for a reasonable span by that process in a joint called tuberculous disease, a process which after many centuries of unjust ignominy is now servilely imitated by the surgeon is his operation of arthrectomy. In the familiar "white swelling" is represented the often successful attempt of the organism to rid itself of the tubercle bacillus by means of the inflammatory process. In this, as in other invasions, the enemy is not repelled without loss, but it is the loss of a part as against the loss of the whole. The philanthropic busybody who, after contemplating the death-roll ascribed to inflammations of the lung and brain and kidney, could succeed in ridding the earth of the process of inflammation, would see a result which hardly a pessimist could regard as kindly. It may be assumed that within a month or so of the disappearance of inflammation from the business of the body the human race would become extinct.

What has been said of inflammation in general applies equally to inflammation within the great serous cavity of the abdomen. Peritoneal inflammation is not a purposeless calamity. That which has caused it is the thing which is wholly ill. It is by the process of inflammation that the advance of certain deadly irritants, which have gained access to the cavity, can be arrested. The purpose of peritonitis is towards the saving of life and not towards the destruction of it. What is seen within the abdomen at the autopsy on a case of peritonitis represents the results of an attempt on the part of the organism to avert a too potent cause of death. It does not represent, as is too commonly assumed, the reckless and fanatical destruction wrought by a wholly evil-tending process.

(a) Delivered Jan. 29, 1894, before the Medical Society of London.

(2) The Relation of Peritonitis to the Inflammatory Process.

In the larger proportion of examples of fatal peritonitis the leading symptoms are those of poisoning and not of inflammation, and death is due rather to toxæmia than to inflammation of the serous membrane. This view of the subject was advanced by Wegner (*a*) nearly twenty years ago.

There is about the patient who is dying of peritonitis every suggestion of a poisoned man. He lies back in bed prostrate, with gaunt cheeks and sunken eyes. There is a look of unceasing anxiousness in his face, and a sense of hopeless unquiet in his movements. The hands, which wander with pathetic restlessness over the bedclothes, are cold and damp. The tongue is that of a man who is dying of thirst. There is constant vomiting. The breathing is laboured, and accompanied with faint sighs and groans, and the countenance is ashen and livid. Such a picture makes a reality of the metaphor of "the shadow of death." So far as the aspect of the patient goes, he might be dying from snake-bite or from the poison of cholera, while there is little to suggest an inflammation so intense as to be ending fatally in a few distressful days.

When the patient dies and the abdomen is opened, the amount of inflammation discovered is out of all proportion to the phenomena which preceded death. In one case there may be merely some injection of the peritoneum with loss of its polished surface, and in its place a general stickiness and a few frail and insignificant adhesions. In another, there may be an ounce or so of thin greenish pus around the cæcum, an exudation looking ill-conditioned enough to the surgical eye, but still a mere scanty mixture of pus and turbid fluid, and not the kind of formidable effusion which would be expected in a case of death from inflammation.

In the human subject, as in the laboratory experiments, it must be remembered that where the question of sepsis is concerned, not only must the dose be considered, but also the power of resistance of the individual.

In further support of the statement that in the larger proportion of the examples of fatal peritonitis the leading symptoms are those of poisoning and not of inflammation, and that death is due rather to toxæmia than to inflammation of the serous membrane, the following points may be adduced.

It is noteworthy that the cases in which suppuration is the most pronounced, are among the most favourable examples of peritonitis, and that on the other hand the most acute and favourable cases are those which show the least inflammatory changes.

In not a few instances of puerperal peritonitis, the cases, if regarded pathologically, are merely examples of septicæmia in the most ordinary sense. In addition to the usual constitutional signs of that condition, there are certain local symptoms which indicate a disturbance within the peritoneum.

Then, again, the surgical treatment of acute diffused peritonitis as a purely inflammatory affection has not been very successful, and has indeed been comparatively unsuccessful. This treatment consists of incision and the evacuation of the effusion. It answers admirably in suppurative inflammation of the purulent peritonitis, as met with in the pelvis and about the cæcum, and in the tuberculous variety, but in the form of peritonitis now under consideration it is comparatively useless. It may be also incidentally mentioned that the mortality attending the operation for strangulated hernia, does not appear—except in connection with umbilical hernia—to have been greatly improved since the introduction of aseptic measures in surgery. These measures, if complete, are assumed to reduce the risks of inflammation in an operation like herniotomy to a minimum.

But even in cases in which neither gangrene nor perforation of the gut occurs, it is evident that there is something besides mere inflammation which is leading to death. It must not be assumed in a contrary direction that inflammatory phenomena are wholly subordinate in peritonitis. In many instances such as those consequent upon troubles in the pelvis or in the vermiform appendix, the signs of inflammation are paramount. There may be an initial rigor, the fever is high, the pain and tenderness are intense, and the production of aggressive pus is often early and vigorous. Moreover, in tuberculous peritonitis the leading symptoms more usually belong to the category of chronic inflammation, and the patient not infrequently dies of suppuration and its consequences. One cannot avoid repeating that these cases represent the more favourable aspects of peritonitis, and that they respond well to those general operative measures which are applicable to inflammation.

In concluding this part of the subject, it is only fair to say that other views of the mode of death in peritonitis are held by many competent authorities, and in illustration of this I cannot do better than refer to the very thoughtful and original monograph on this subject by Dr. John Malcolm (*a*), who contends that to nervous disturbances must be referred many of the conditions which have just been discussed.

The Peculiarities of the Peritoneum.

It is obvious that there are phenomena attending a lesion of the peritoneum which a reference to like disturbances in other serous membranes cannot explain.

Both pleuræ may be violently inflamed, and that inflammation may run on to suppuration, and yet the condition has not the gravity of a case of peritonitis in which the evidences of inflammation may be slight, and in which the exudation, if collected, may only amount to a few ounces of sero-purulent fluid. Even when the necessary allowance is made for the greatly different extent of surface in the two cavities, an explanation of the differences in the relative prospects of death is not forthcoming. It will be said that the gravity of the two cases depends, not upon a damage to the serous membranes, but upon a resulting disturbance of function in the viscera they cover. From this point of view peritonitis may be considered to be more aptly compared with inflammation of the meninges of the brain. But even this comparison is not entirely satisfactory. That death must follow a gross interference with the functions of the brain is obvious, but it is not so evident that those who die of peritonitis die because the functions of the abdominal viscera are gravely disturbed. We do not encounter in peritonitis such fatal functional disturbances as suppression of bile or suppression of urine. In a case of acute peritonitis ending in death in four days we have, for that time the following evidences of abdominal disorder. There is constant pain, and frequent vomiting, and absolute constipation, and the ingestion of no food. But a patient may be in pain for four days, and may be starved for four days, and may vomit for four days, and have no action of the bowels for four days, and yet live. So far as functional disturbance of the viscera within the belly is concerned, it is safe to say that in many cases of severe lead poisoning which end in recovery, the visceral disorders are more considerable than they are in some examples of peritonitis which end fatally in a few days.

Then, again, septic matter often finds its way into the pleural cavity. It is true that serious symptoms may follow, but they are by no means of necessity fatal, and are certainly not to be compared in gravity and deadliness with the results of introducing a part of the same septic matter into the peritoneal cavity.

(*a*) *Arch. fur Klin. Chir.*, 1876.

(*a*) "Medical Society's Transactions," vol. xvi., 1893, p. 188.

The following points may be noted with regard to the peritoneum:—

1. Its surface is very considerable, and is probably, as Wegner (*a*) states, as great as that represented by the whole integument of the body.

2. The membrane possesses remarkable powers of absorption, as shown by the manner in which milk, blood, peptones, &c., are taken up. It is said to be capable of absorbing an amount equal to from 3 to 8 per cent. of the body weight. It is noticed that septic intoxication occurs quicker in peritoneal infection than in any other. Dirt, pus, fæcal matter are more dangerous to life when introduced into the peritoneal sac than when brought into contact with any other like cavity.

3. The peritoneum offers a limited resistance to septic organisms and their products. Experiments upon animals and clinical experience in man show that it can safely dispose of a certain quantity of septic germs. The precise process by which this is effected is a matter of some doubt. There is evidence to show that the resistance of the peritoneum varies within wide limits, and is affected by age, and by such enfeebling disorders as chronic liver or kidney disease. The peritoneum of the rabbit appears to be remarkably sensitive to sepsis, whereas that of the dog has comparatively high powers of resistance. The intestinal mucous membrane affords an infinitely less sensitive medium for septic infection than does the serous covering of the bowel.

4. No tissue in the body provides more favourable conditions for healing than does the peritoneum.

5. The peritoneum does not show the same degree of vulnerability in all parts, nor are all portions of it alike in the manner in which certain lesions are responded to. The part which is apparently most sensitive to infection, and which is most prone to rapidly spreading and diffuse inflammation, is that which covers the small intestine. The parietal peritoneum has certainly not so high a degree of susceptibility, and is not so apt to assume the diffuse and low form of inflammation.

6. The peritoneum appears to be possessed of great sensitiveness—a matter of moment in the production of shock. This sensibility is evidently peculiar and is not quite comparable to that possessed by the skin. Certainly the peritoneum does not feel pain as does the skin.

The twisting of a hernial sac and the securing of it with a tight ligature is seldom followed by much distress, and yet the same process carried out on integument of equal extent would assuredly be attended by considerable nerve disturbance. The pain which may accompany the injecting of a large hydrocele with iodine is noteworthy.

The handling of perfectly normal peritoneum is attended with more or less distress in conscious patients. This is illustrated in iliac colotomy performed without anæsthesia, in the reduction of prolapsed coils of intestine covered with unaltered peritoneum, and especially in the removal of gauze tampons. When the surface of the serous membrane has become inflamed and covered with lymph, the ordinary sensibility appears to be dulled or lost. This is noticed in the decrease of pain and tenderness which is not uncommon as a plastic peritonitis advances, and also by the fact that in iliac colotomy or gastrotomy carried out in two stages, the cutting of the gut or of the stomach when once it has become covered with lymph, is more or less entirely painless. The irritant which of all others appears to affect the peritoneum the most acutely, is that represented by the invasion of the surface by certain bacteria or by their products. The disproportion between the intensity of the pain and the comparatively small area of infection, is often to be well seen in cases of disease of the vermiform appendix.

7. One matter of great interest, although of some obscurity, concerns the condition of pressure within the abdominal area, and the effects which follow upon the disturbance of it. It has been many times pointed out that there is no cavity of the abdomen, and that the term, the sac of the peritoneum, is a misnomer. "Every practical anatomist," wrote Benjamin Travers nearly a century ago, "has a familiar illustration of the non-existence of an abdominal cavity in the operation of laying open the abdomen." (*a*)

In performing laparotomy, the surgeon is constantly reminded that he is cutting into a vacuum and is exposing what is merely a potential cavity. This appears to be more noticeable when the operation is quickly done. I have the impression that when the serous membrane is fully exposed and yet undivided, air may pass through it into the potential space. Some invisible damage may have been wrought by the forceps in some of the more striking instances. Sometimes, especially in a child, a loop of gut may be seen through the peritoneum to be lying in the very closest contact with it. A minute prick is made, and the gut seems to fall away from the membrane and a cavity is revealed.

One would imagine that the disturbance of pressure relations of this kind, could not be without effect upon the sensitive tissues and thin walled blood vessels within the abdominal parietes. The effect of a mere incision into the abdomen is often entirely remarkable. In not a few cases of tuberculous peritonitis a simple laparotomy has been performed, the fluid within the abdomen has been allowed to escape, and the wound has been hastily closed. Yet to the surprise of the operator this elementary proceeding has been followed by complete cure. (*b*) What explanation is there to give?

The examples in which complete and quite unexpected relief of abdominal troubles has followed the mere opening of the peritoneal space are numerous. Many remarkable instances have been collected by Professor William White, of Philadelphia, in an interesting paper on the curative effect of operations *per se*. (*c*) If all those cases of cure by simple incision be excluded in which a neurosis may have been the foundation of the trouble, there still remain many instances in which the assumption is very strong, that considerable physical changes within the abdomen must attend the mere opening of the cavity.

There are certain other points in connection with intra-peritoneal pressure which remain to be mentioned. In the first place, gravity does not appear to follow the usual lines within the abdomen. One would expect that any effusion which is free within the cavity of the belly would find its way into the pelvis as the most dependent part, and that this would take place even in patients who are lying in bed. It is quite obvious that adhesions must much influence this matter. At the same time, the great frequency with which this action of gravity appears to be inoperative, or at least imperfect, is so marked as to call for some explanation. In the second place, the frequency with which escape of fæces fails to take place in spontaneous perforation of the intestine and in punctured wounds of that viscus is somewhat remarkable. Travers (*d*) lays especial stress upon this, and gives several illustrative cases. He is of opinion that the explanation is to be found in the state of pressure within the abdomen.

Zeigler (*e*) states that in fifteen cases of laparotomy

for wound of the intestine, fæcal extravasation was found to have taken place in six instances only. He also considers that this is to be accounted for by pressure, and alludes to the observation of Klemm, (*a*) who asserts that the idea that the wound in the bowel is blocked up by prolapsed mucous membrane is fallacious.

8. The last point concerns the possibility of the peritoneum acquiring some degree of immunity from septic infection. It has been shown by Reichel (*b*) and others that in dogs an immunity from peritoneal infection from pyogenic cocci can be produced artificially. A small dose of septic material is introduced into the abdominal cavity, and after the animal has recovered from the disturbance produced a large dose is injected. This process is repeated at intervals with increasing amounts of the poison, until at last no symptoms are induced by an amount which, in a control experiment, would cause death within twenty-four to thirty-six hours.

A not unlike invulnerability appears to be possible in the human subject. Other things being equal, an operation carried out within the abdomen of a person who has had chronic peritonitis, or who has exhibited repeated subacute attacks, and whose peritoneum presents substantial adhesions, is likely to be attended with better results than when the peritoneum is found to be wholly undisturbed. In the operation for removal of the vermiform appendix in cases of relapsing typhlitis, the little disturbance which follows extensive procedures occupying as long as one hour and a-half can, I think, be explained only by an immunity acquired by the peritoneum after repeated attacks of inflammation. Moreover, in advanced cases the disproportion which is often noted between the constitutional disturbance and the local condition discovered at the operation appears to be capable only of the same explanation.

I have reported (*c*) the case of a woman with a fæcal fistula, due to the destructive suppuration of a dermoid cyst of the ovary. I opened the abdomen for the purpose of closing the fistula. The tract led down to a hole in the sigmoid flexure, which was firmly fixed in left iliac fossa. As the bowel could not be brought to the surface, and as the opening could not be sutured *in situ*, there was nothing to be done but to leave it, and to back the area between the hole in the bowel and the parietal wound with iodoform gauze. Very extensive adhesions existed, and for some twelve months previously there had been a smouldering peritonitis. The patient did well, and the good result was probably to no small extent due to the immunity the peritoneum had acquired during the twelve months of inflammatory turmoil.

In looking over the records of laparotomy performed for perforations in the stomach or bowel it is impossible not to be struck with the fact that in many of the successful cases there had been long antecedent visceral or peritoneal trouble. (*d*)

PREPUTIAL WARTS.

By TOM ROBINSON, M.D.

We are all familiar with cases of warts occurring at those parts of the body where the skin loses its type and passes into the mucous membrane (*cutaneous borderland*). A good example of this hybrid tissue is under the prepuce and at the end of the penis, and here we often find warts growing with singular rapidity and exuberance, sometimes obtaining sufficient size to prevent the foreskin being drawn over the end of the glans. These warts are frequently found in those who have been exposed to venereal maladies, whilst in others they will occur where there is neither suspicion or possibility of such a cause. Most frequently they appear in individuals where the prepuce is long and constantly covers the corona. Moreover, in the absence of scrupulous cleanliness the secretion from the sebaceous glands in this position decomposes and gives rise to an offensive odour resembling that of mice.

We do not remember to have seen a case in anyone over 30 years of age, and, as a rule, they have been met with in individuals about 20 to 25. If the organism is tainted with syphilis the warts will be influenced by the poison, but not in such a way as to give them distinctive clinical characteristics.

The chief object in alluding to this very common ailment is to draw attention to the treatment. There are two distinct courses open to us :—

A. To cut off the warts and apply a caustic.

B. To apply local remedies.

The first appears the most attractive, and it will frequently be successful in one sitting, but there are difficulties of procedure caused by the very copious bleeding, or by the way in which the warts often nestle down by the side of the foreskin. After operation, moreover, in not a few cases your patient finds the warts growing almost if not quite as exuberantly as ever.

The local remedies have been in some cases unexpectedly successful, and have produced a cure without the loss of any time.

The application of the stronger caustics, such as chloride of zinc, has not been found practicable, whilst the strong acids have run into the surrounding tissues in spite of every care.

We have in the first instance ordered a powder composed of equal parts of acetate of copper, powdered savin leaves, and starch, to be dusted over the warts for four consecutive mornings ; the effect is to eat down the warts. The patient was afterwards directed to wash away any secretion twice a day, and to keep the following powder over the under surface of the prepuce and glans penis for a couple of weeks. The second powder is composed of half a drachm of tannin, half a drachm of camphor, half a drachm of powdered savin, mixed with six drachms of oxide of zinc.

Selected Prescriptions and Therapeutic Notes.

48.—Thiersh's Antiseptic Solution :—

℞ Acid. salicylatis, ʒss ;
Acid. boracis, ℥ss ;
Aq., ad ℥viij. M.

49.—Some Points in the Treatment of Influenza :—In catarrh of the upper respiratory tract a pill of belladonna, camphor, morphia, and quinine every two or three hours gives speedy relief.

In all stages of the disease whisky is the remedy *par excellence*, to counteract the great prostration, and should be given three times a day throughout the attack. If whisky is not well borne give champagne, brandy, or sherry.

In the musculo-neuralgic variety of influenza we have a specific in the pill of phenacetin and salol, two grains and a half of each every three hours.

The drugs antipyrine, antifebrine, or phenacetin, whenever administered to relieve the headache, fever, and muscular and neuralgic pains, should be given with whisky, as the latter hastens their action and tends to counteract their depressing effects.

When the muscular pains are obstinate salol in five grain, or salicylate of soda, in fifteen-grain doses three

Clinical Records.

THE WHITWORTH HOSPITAL, DUBLIN.

Case of Locomotor Ataxy with Charcot's Disease.

Under the care of Dr. G. P. L'Estrange Nugent.

An army pensioner, æt. 49, admitted to the Whitworth Hospital, December 28th, 1892, complaining of swelling in right knee and general difficulty of walking. No history of syphilis, excess of any sort, or heredity.

About three years before admission symptoms commenced, which gradually increased. Weakness and difficulty in walking—first in left leg, then in right—accompanied by lancinating pains and slight bladder trouble. Later on periodical fits of "choking," which were laryngeal in character, and which started, as he described, from the pit of his stomach.

Three months before he came under observation he got a fall off a vehicle striking his right knee against the ground, and at that time felt something give. The knee rapidly swelled, but was almost painless. It increased or diminished in size from time to time, and in about six weeks after the accident commenced to bend backwards.

His symptoms while in hospital were briefly these. His voice was impaired from paresis of the adductor muscles of the larynx, and speech thick from apparent deficient tongue movement. Pupils markedly myotic ; Argyll-Robertson phenomenon well developed ; and slight ptosis of both upper eyelids. Severe pains in the stomach and constipation. Frequent micturition, especially at night—urine containing large quantity of pus and sometimes a little blood—and occasionally incontinence. Ordinary sensation is diminished and distinctly delayed to a smart prick of needle. Slight paræsthesia, such as tingling, &c., and occasionally allocheiria. Knee-jerks are lost, and plantar reflexes diminished.

His gait was considerably modified by the condition of his right knee, and he could only progress with extreme difficulty with the aid of two sticks, and when he rested the weight of his body on his right leg. the retroflexion of his right knee was so great as to cause apprehension of the condyles of his femur, which projected strongly backwards, bursting through the skin. The knee in circumference measured four or five inches more than that of the opposite side, and this increase, due chiefly to fluid effusion, would considerably subside after some days' rest in bed. The veins over the joint were considerably distended, and the ends of tibia and fibula could be felt to be enlarged. The patient ultimately sank from urinary complications, and died in April, 1893. The autopsy revealed the following condition of the knee-joint :—

The muscles in the neighbourhood of the joint were well developed. Capsule greatly thickened, especially on either side of the ligament patella. External lateral ligament thickened ; internal, normal in appearance. On the joint being opened the synovial membrane was found to be much thickened, both the part covering the non-articular surface of the bone and that lining the capsule. Numerous small bands passed across at the angle of reflexion. Small pedunculated bodies, hard to the touch, projected into the joint cavity. Near the patella the membrane was roughened, and had a warty appearance. The lower end of the femur was greatly enlarged, the cartilage covering the articular portion was eroded in parts, and eburnated bone shone through.

The margin of the articular surface above projected abruptly, was irregular and lipped, and overhung the non-articular surface of the femur. On looking at the posterior surface of the joint large synovial fringes overlapped the condyles, the cartilage was eroded in parts, and in other places elastic elevations projected from it ; irregular bony outgrowths were found along the upper part of condyles. The patella is transversely enlarged, slightly diminished in size from above downwards ; its cartilage was partially eroded, and a bony lip of the same character as that on the femur projected from its upper border.

The lip of the tibia was enlarged ; the cartilage on the upper surface was eroded in a similar manner to that on the femur, and bony outgrowths appeared between the tuberosities. The anterior crucial ligament had disappeared, the posterior also to a great extent, and the femur could with ease be luxated backwards to a very considerable degree. The semilunar cartilages appeared to be intact.

The spinal cord, examined by Dr. Alfred Scott, presented the usual appearances found in locomotor ataxy. The posterior columns in all parts were degenerated. In the cervical and dorsal region the postero-internal columns were in an extreme condition of degeneration, while the postero-external columns were less so. In the lumbar regions both columns were equally degenerated, but not so much as the postero-internal columns higher up.

The cells in the anterior cornua of grey matter stained badly, and many of the cells in those parts throughout the cord were pigmented and granular. There did not appear to be any degeneration in the cerebellar tract or elsewhere, except as mentioned above.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, January 12th.

Sir W. Stokes in the Chair.

FIBROUS STRICTURE OF THE ŒSOPHAGUS TREATED BY GASTROTOMY AND DILATATION FROM BELOW.

Mr. Kendal Franks read a paper on Fibrous Stricture of the Œsophagus treated by Gastrotomy and Dilatation from below. The patient, a young lady, æt. 24, had suffered from dysphagia ever since she had had scarlatina, when seven years of age. Symptoms had during past two years been progressively worse, and she was reduced from 8 stones to 5½ stones in last 12 months. Bougies introduced showed a practically impermeable stricture 3 inches above cardiac orifice. On July 6th, 1892, abdomen was opened in middle line from xiphoid cartilage downwards. The stomach, very contracted, was opened for about an inch, cleaned out, and the finger introduced. The stricture was found 3 inches above cardia. Otis' dilating urethrotome, without the blade, was passed along the finger through the stricture, and the stricture was dilated first antero-posteriorly and then laterally. A bougie passed through the mouth emerged in the stomach and by its means strong silk drawn up the œsophagus to the mouth. A plug of gauze tied to this, with another silk ligature at the other end, was drawn backwards and forwards through the stricture, and was finally left in the stricture, the lower ligature being cut off. The stomach was immediately closed, returned to abdomen, and the external wound sutured. The plug was withdrawn in six hours. The patient made an uninterrupted recovery, and was able to go out on the 21st day. Two months later the stricture readily admitted a medium-sized bougie. Dilatation, supplemented by electrolysis, was carried on at intervals. The patient, 18 months after operation, was in perfect health, and had increased in weight from 5½ to 8½ stones. The author exhibited a table he had prepared of all the cases hitherto published which he could find; they numbered 21. Eight of these had been done by the immediate method, same as the case recorded. In the remainder a gastric fistula had been first established, and subsequently, from one to four months, retrograde dilatation of the œsophagus, either by Hagenbach's or some other method, had been carried out. The author argued in favour of the immediate method in all cases of impermeable fibrous stricture, except after extensive injuries involving a great length of the tube, when immediate dilatation would be impracticable.

Sir W. Stokes said there were many points of surgical interest and importance in this paper. There were three to which he might direct attention. The first of these was as to the relative merits of gastrotomy or gastrostomy in cases where the retrograde dilatation was to be performed. He gathered that Mr. Franks was in favour altogether of gastrotomy, and he was inclined to agree with him, because, where dilatation was to be performed, there were much greater facilities by performing gastrotomy than where they would have to work their way through a comparatively small fistulous opening in the stomach. Then again, in cases where gastric fistula is established there was always great difficulty in getting it to heal. The next point that occurred to him—and he hoped Mr. Franks would not think he was going to throw any doubt upon the accuracy of his diagnosis—was, that it struck him as being very remarkable, if this was a case of fibrous stricture of the œsophagus of nearly over 17 years' standing, that it should be so very amenable to the treatment of dilatation, and in that respect differing so much from what they knew by experience to occur in cases of stricture of other organs, particularly that of the rectum and urethra. Here they had a case of great chronicity, and on the 21st day after operation the patient was perfectly well. It was very exceptional, assuming it was a fibrous stricture, and he would like to hear Mr. Franks in reference to the possibility of its being a spasmodic closure of the œsophagus. This condition was by no means infrequent in persons of a neurotic tendency. There was one other point he would wish to allude to, and that was to the operation of œsophagotomy in cases where the stricture occurred close to the cardiac end. And although the operation required a considerable degree of anatomical skill, still the dangers of the operation were not so great as in gastrotomy. By opening the œsophagus low down they would have as much facilities for dilatation as through the stomach. He merely threw out the suggestion, and he would like to have Mr. Franks' opinion on the point.

Mr. T. Myles thought there was nothing more difficult than to arrive at a correct diagnosis regarding obstructions in the œsophagus. The most experienced surgeons had erred in these intra-thoracic obstructions, and even allowing that the diagnosis is made, they had then to learn whether the obstruction was benign or malignant. He also thought the relations of the œsophagus to the diaphragm very important, and in many cases stricture of the œsophagus, close to the cardiac end, was due to some interference with the normal physiological opening in the diaphragm. Many of those cases which were cured by electricity and bougies, were merely strictures comparable to the "stammering" of the bladder in retention of urine. He believed Mr. Franks' case to be one of *bonâ fide* stricture successfully treated. He submitted that owing to proximity of great vessels and nerves to the œsophagus, and to the fact that an instrument must form an acute angle with the œsophagus, the dangers of œsophagotomy were much greater than those of gastrotomy. He failed to see any analogy in stricture of the urethra, because in the latter case they had a canal composed of unyielding structures, and subject to the passage of irritating matters

Mr. F. A. Nixon thought that the dilator should not be used as long as the finger could reach the stricture. He found from examinations on the dead subject as well as from Mr. Myles' case, that when the hand is passed into the stomach with the finger in the œsophagus, the cardiac auricle rested in the palm of the hand, and very slight pressure would cause it to perforate the œsophagus and wound the auricle. He thought the operation of gastrotomy much more simple than opening the œsophagus.

Mr. Tobin said that among the various measures enumerated for the cure of the stricture, no mention had been made of leaving in a tube for a considerable length of time with a view of bringing about gradual enlargement of the stricture. He thought the passing of the threads through the œsophagus, and into the opening in the stomach, a very admirable method; but if a full-sized instrument occupied the place of the thread its pressure might bring about absorption, just as occurred in urethral stricture. The operation, as suggested by Mr. Franks, seemed to him to possess great advantages, because, even if they failed to get the stricture dilated they would still have means left of getting food into the stomach, which would not exist where œsophagotomy was performed.

Mr. Wheeler said he could not agree with Mr. Myles as to the difficulty or danger of œsophagotomy. He performed the operation on four different occasions, and he avoided all the vessels which Mr. Myles dreaded so much. He thought the best method of keeping the wound aseptic was to drain with catgut. The question to his mind was, whether they could dilate a stricture three inches from the stomach by opening the œsophagus through the neck.

Mr. M'Ardle said that in performing the operation of œsophagotomy he had no difficulty, but he had a good deal in guiding a bougie through the stricture. He opened it high up on account of cellulitis having occurred where the opening in the œsophagus originally occurred. In dilating the œsophagus, he found it easier to work from the mouth —and why perform the operation when they had a natural opening above?

Mr. Kendal Franks, in reply, said his paper did not deal with the question of œsophagotomy, but he thought it was quite proper to discuss whether œsophagotomy might not possibly be a better method than gastrotomy. He was quite well aware that Mr. Richardson, of Boston, maintains that it is much easier to reach the stricture through an opening in the œsophagus than through the mouth, and that the bougie can be passed with much greater ease. His (Mr. Franks') great objection to œsophagotomy, as compared with gastrotomy in cases of almost impermeable stricture, was the difficulty of finding the small opening from above. They might sometimes as well look for a "needle in a bundle of straw" as find the small opening from above. But when dealing from below, it was comparatively easy to pass the bougie, because they had not a dilated œsophagus to deal with.

SOME INTERESTING CASES OF GUNSHOT WOUNDS.

Mr. Austin Meldon read some notes on cases of this class:—

1. A boy was accidentally shot, the bullet entering the abdomen to the right of the sternum at the lower end. Peritonitis and escape of bile followed. The fistula closed, and he was discharged in a month.

2. A woman was shot in four places. One bullet passed through the muscles of the right arm; the second lodged in the wrist; the third entered between umbilicus and spine, and was removed from the groin; the fourth entered to the right of the sternum, passed through the lung, and was found in the muscle on the left side. She recovered.

3. A man accidentally shot himself. The bullet entered on the right side of the thorax above the nipple, and passed into the lung. He recovered.

Mr. Myles mentioned the case of a young policeman who was shot in the right side of the neck under the sterno-mastoid, and the wound healed perfectly. He had paralysis of the right arm, and all the time confidently asserted that the bullet was in his neck. His view was the correct one, for the bullet was extracted a considerable number of years after by another surgeon. Another case was that of a man struck in the thigh, and the bullet ran in the line of his femoral artery. He suffered from no pain or trouble, and the wound healed up with the bullet still in the leg.

Mr. Tweedy mentioned the case of a young man who shot himself in the park, and subsequently walked to the hospital. There was a hole below the right nipple and a lump on the side of the spine, indicating where, as they thought, the bullet was. He died of peritonitis, and it was found that the bullet had gone through both walls of the stomach.

Mr. Wheeler mentioned a case of a young man shot below the ensiform cartilage who recovered. He was also called to a case in Kilkenny, where an officer was shot through the temporal region, and the bullet lodged in the brain. He had no symptoms save that he could not speak, and that there were some slight twitchings of the face. He passed a probe and hit the bullet, but refused to operate on account of the absence of symptoms. The patient was now quite well. He next referred to a gamekeeper who shot himself with a revolver on the side of the neck. He got aphasia and paralysis of the right arm and leg. There was no aperture of exit, so he adopted no treatment, and the man got gradually well. His next case was one in which a man shot himself in the gluteal region, and the bullet travelled round towards the great trochanter. He removed it along with the anterior and external portion of the femur. His next case was a penetrating wound of the lung, and whenever the person spoke a hissing noise could be heard at the back of the lung.

Mr. F. A. **Nixon** mentioned the case of a young man brought into hospital suffering from a very slight wound in the foot, with some discolouration. He was walking in a procession, and thought that somebody must have trod on his foot. The wound was dressed, and subsequently an abscess formed. At the bottom of it they found a revolver bullet.

Mr. **Wheeler** also referred to a bullet found in the pericardium of a man who died in Baggot Street Hospital. He received it at the battle of Salamanca.

Mr. **Kendal Franks** mentioned the case of an American who came to him some years ago to have a bullet removed from the frontal sinus. He had apparently attempted to commit suicide by holding a revolver beneath the jaw and firing upwards—that was about two months previously. The track of the bullet was manifest. It had gone through the tongue, through the hard palate, up through the left nostril, and entered the left frontal sinus. The point of the bullet had impinged on the edge of some bone, because it was found split, and the bullet had turned completely round so that its apex was downwards.

The Section then adjourned.

◆

LARYNGOLOGICAL SOCIETY OF LONDON.

Annual General Meeting held Wednesday, Jan. 10th.

Dr. **Felix Semon**, M.D., F.R.C.P., Vice-President, in the Chair.

The Treasurer's Annual Statement was presented and adopted.

The expenditure for the year had been £98 6s. 8d., and the income £114.

The Librarian reported the presentation of several works to the Society's Library.

The following were elected as Officers and Council for 1894:—President—Felix Semon, M.D.; Vice-Presidents—P. McBride, M.D.; W. McN. Whistler, M.D.; Treasurer—H. T. Butlin, Esq.; Librarian—F. de Havilland Hall, M.D.; Secretaries—E. Clifford Beale, M.B.; Scanes Spicer, M.D.; Council—E. Cresswell Baber, M.B.; A. Bronner, M.D.: Dundas Grant, M.D.; T. Mark Hovell, Esq.; C. J. Symonds, Esq.

An Ordinary Meeting of the Society was subsequently held, the President, Dr. Felix Semon, being in the Chair.

Dr. **Bronner** exhibited some laryngeal syringes which had been so constructed as to admit of their being rendered aseptic by boiling. He also showed some portions of deviated septum removed by means of a cutting trephine, which he had found useful in dealing with such cases.

RHINITIS ATROPHICA FŒTIDA WITH APHONIA.

This case was exhibited by Drs. **Hill** and **Cagney**. A. H——, æt. 24, a domestic servant, had suffered from dry nose and throat for four years and a half; aphonia three years. In May, 1893, she was found to have rhinitis sicca, pharyngitis sicca, and laryngitis; under appropriate *local* treatment these conditions were improved, but the aphonia was unrelieved, and recently neuralgia of the left side of pharynx and head had become developed. Faradism and galvanism to the larynx had been used persistently three or four times a week for about two months with no practical benefit. Suggestions were invited as to best line of treatment.

Dr. **Dundas Grant** considered the laryngeal condition secondary to the disease of the nose. The aphonia was a remnant of the laryngitis so caused, and he believed that after successful treatment of the nasal suppuration, the laryngeal condition would yield to the judicious use of local applications and electricity.

Dr. **Bronner** mentioned that such cases were very common in Bradford. Of about 250 cases, at least 40 would be cases of dry catarrh, but he had seen many cases where the larynx was alone affected, and which were successfully treated by intra-laryngeal injection.

The **President** was not convinced of the connection between the nasal and the laryngeal trouble in this case. The aphonia was still complete although the crusts and dryness were no longer visible.

Dr. W. **Hill**, in reply, agreed with the President's view. He did not think that the laryngeal affection was simply secondary to a suppurating sinus. There appeared to be a general atrophy of the mucous membrane.

Dr. A. A. **Kanthack** read notes on "The Function and Anatomy of the Epiglottis," and was followed by Dr. **Percy Kidd**, who showed a case of

RECURRENT PAPILLOMA OF LARYNX TWICE OPERATED ON BY THYROTOMY.

Chas. W., æt. 9, was admitted into the Brompton Hospital on Sept. 7th, 1893, on account of loss of voice and slight inspiratory stridor. His voice had been lost since April, 1893. Laryngoscopic examination showed the presence of growths on the anterior portions of both vocal cords, especially the right. On Sept 19th Mr. Godlee performed thyrotomy, and removed the growths with a sharp spoon. Rapid healing ensued, but the growth recurred twice in the next three months, and was each time removed by thyrotomy. Microscopically the growth was a papilloma.

Mr. **Butlin** recalled two cases in which he had performed thyrotomy on the same day. In one the operation was simple and successful, with good recovery of voice. In the other case the growth was diffuse and difficult to distinguish from healthy tissue; it was removed by scraping, but recurred again and again, and the patient was now wearing a tracheotomy tube.

Dr. **Dundas Grant** would attack the growth by means of his safety endo-laryngeal forceps under anæsthesia, and at the same time administer arsenic.

Dr. **Scanes Spicer** thought that the growth might be removed endo-laryngeally, and recommended the use of chloroform supplemented by frequent mopping with cocainised mops to produce complete anæsthesia and paralyse secretion.

The **President** mentioned a case in which no less than seventeen thyrotomies had been performed on the same patient, the result after each being simply recurrence of the growth. He agreed that Dr. Kidd's case might be treated endo-laryngeally with Dr. Dundas Grant's forceps. As a general rule he would prefer to leave such growths alone in young children, unless they were causing dyspnœa. Although brilliant results might occasionally occur, recurrence generally took place, and perpetual operations had to be performed. Even where there was dyspnœa it was sometimes better to perform tracheotomy and wait until the child grew older before removing the growth.

Dr. **Percy Kidd** next showed a microscopical section of a portion of a tumour showing the characters of an "angioma," which had given rise to hoarseness and a sore feeling in the throat for twelve months. Laryngoscopic examination showed a rounded tumour of the size of a pea springing from the left vocal cord, about the junction of the anterior and middle thirds. The growth presented a pinkish grey colour, and was attached by a broad flat pedicle which permitted a considerable degree of movement. The tumour was removed in two pieces with Mackenzie's cutting forceps, under cocain. No bleeding of any note resulted. Three days later the left vocal cord presented a reddish irregular appearance, but no trace of the growth remained.

Mr. L. A. **Lawrence** showed a patient with enlargement of posterior faucial pillars, a man-servant, æt. 30, who had suffered as long as he could remember with his throat. The tonsils were large. Posterior faucial folds very large, smooth, red, and hard to the feel, and extending some considerable way down the back wall of the pharynx. Uvula also swelled. Vocal cords normal. The turbinate bones were slightly enlarged, but the nostrils not blocked. The pharynx was greatly narrowed by the projection of the large posterior pillars.

LARYNGEAL PAPILLOMATA.

Dr. **Scanes Spicer** exhibited a pathological specimen from a schoolgirl, æt. 8, who lost her voice during an attack of measles, and whose right vocal cord on its upper surface and inner margin was covered with sessile warty growths. After removal by Mackenzie's lateral forceps, her restoration to health of voice and larynx was perfect.

Dr. **Scanes Spicer** also exhibited a pathological specimen of papilloma of uvula in a girl, æt 15.

CARCINOMA OF THE ŒSOPHAGUS.

Mr. W. R. H. **Stewart** exhibited this specimen, L. G—, æt. 29, a cook, an anæmic and somewhat emaciated woman, who stated that in February, 1893, she had a sore throat, with dryness and difficulty of swallowing, taking fluids better than solids. She began to lose flesh, and the food occasionally regurgitated through the nose. There was no history of syphilis or injury to the throat of any description. The father and one brother died of phthisis. The voice was hoarse. There was tenderness over the right side of the larynx, and she expectorated a white frothy fluid. Laryngoscopic examination showed some irregular swellings about half an inch above the arytænoids to the right of the middle line, and from one point pus was oozing; through this a fine probe could be passed into the œsophagus, some roughness being felt as it went through. Larynx normal. Patient gradually got weaker, the difficulty in swallowing, tenderness and pain in the right side of the neck increased, and there was a good deal of swelling in this region. On July 21st, the swelling in the neck having increased, Mr. Stewart dissected down to it, and found a mass of tough, thickened tissue, which proved to be the thickened wall of the œsophagus. This was removed, and a large drainage tube inserted; but the patient gradually got worse, and it was found impossible to feed her either through a catheter or by the tube in the wound: gastrostomy was performed by Mr. Macready, and a good meal was given through the tube during the operation; she seemed greatly relieved, but gradually sank, and died two days after. *Post-mortem*.—The upper portion of the œsophagus for about four inches was found to be affected, and the microscope proved the growth to be carcinoma. There were several points of interest in this case. First, with regard to the unusually early age—twenty-nine. The disease was thought to be very rare before thirty-five years, and although it occurred earlier in women than men, forty-five to fifty-five was the usual time. Again, it was an instance of the reputed disposition of children of tuberculous parents to develop cancer of the œsophagus. There was no traceable exciting cause, and the disease did not spread from an adjacent organ.

Mr. **Symonds** showed a man, æt. 45, with syphilitic stenosis of the larynx of recent origin. There was a general diffused thickening of the mucous membrane, with much narrowing of the glottis and impeded respiration. The affection had existed for one year, and though so recent had not yielded to a vigorous course of remedies. A prophylactic tracheotomy was recommended.

Dr. **Watson Williams** (Bristol) brought forward a case of epithelioma of the soft palate and fauces in a patient æt. 65. The main portion of the growth showed light pink, granular, but deep ulceration, covered with greyish mucopus and disintegrated tissue which gave a characteristic fœtor to the breath. The surface of the ulcerated portion was fissured, nodular, and of a cauliflower aspect, while the margin was seen to be elevated, distinct, and hard. There was no glandular enlargement or infiltration in the neck at first, nor was the pain intense. It had been relieved by iodide of potassium for a time, and when it became more severe by ten-grain doses of analgen. The growth gradually spread and disintegrated. The gland of neck became rapidly involved, and the patient sank and died two months later. An attempt was made to arrest the growth by inoculations with pure cultures of the *Streptococcus erysipelatosus*, but without success.

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, Feb. 2nd.

Dr. **Travers**, Vice-President, in the chair.

The following specimens were shown:—

Dr. **Clemow**: "Perforated Gastric Ulcer."

Mr. J. R. **Lunn** showed the following;—

I. *Perforation of Sigmoid Flexure.*—The specimen was removed from an old man, æt. 72, who died soon after admission into St. Marylebone Infirmary, January 2nd, 1894. At the post-mortem, the abdomen was distended with flatus, and fæces were found in the abdominal cavity. It was noticed that the descending colon was about ten yards long. About nine inches from the anus was found a large perforation into a gangrenous condition of the gut, and its interior was completely blocked by hard fæces, the anus was surrounded by an ulcerating growth, *i.e.*, malignant, which had, however, not produced obstruction. The other viscera were not examined.

II.—*Perforation of Vermiform Appendix.*—The specimen was removed from a boy, æt. 9½, who was admitted into St. Marylebone Infirmary in a dying condition, July 17th, 1893. He was taken ill four days before admission with abdominal pains and sickness. Bowels had not been open for ten days. *Post-mortem*—Abdomen was distended, viscera normal; the intestines were moderately distended, some recent lymph was found amongst the coils of the small intestines, and some offensive pus was found in the pelvic cavity between the left iliac fossa and abdominal walls. The appendix vermiformis was four inches long, around which was some lymph and pus. No perforation was found, but the appendix contained ten round deposits, *i.e.*, concretions. The post-mortem showed that there had been appendicitis, followed by suppuration, which had ruptured into the pelvic cavity, causing death, which was evidently accelerated by the boy's removal in the cab to the infirmary.

III.—*Perforation of Stomach by Primary Cancer of Pancreas.*—The specimen was removed from a man, æt. 35, Jan. 5th, 1894, who had died suddenly of internal hæmorrhage. During life he had no physical signs. At the post-mortem all the viscera were anæmic and bloodless, except the stomach and intestines, which were full of clotted blood. On lifting up the liver, it was found adherent to the stomach, the pancreas was also adherent to the stomach, and had ulcerated through into the stomach cavity; this ulceration had eaten into some large blood-vessel causing the internal hæmorrhage. The œsophagus was healthy and not obstructed. The pancreas was adherent to the surrounding structures, and was replaced apparently by a new growth, *i.e.*, malignant. No secondary deposits were found in the body.

Mr. S. **Paget**: showed a specimen of "Sarcoma of Femur."

Mr. **Alban Doran** read a paper on

THE FEEDING OF PATIENTS AFTER ABDOMINAL SECTION.

The author remarked that the importance of care in after treatment was universally recognised, and diet was the most essential feature in after treatment. The surgeon had to consider how shock might best be counteracted by dietetic means; how much the stomach could bear; and how far the peritoneum and intestines could be left undisturbed. In old and feeble patients, and in any subject after long and severe operations, the starving system was dangerous, nor was food well tolerated by the mouth. Beef-tea enemata were excellent in such cases. These nutrient enemata fed the patient, counteracting the dangers of shock. They allowed the stomach to rest, saving that organ, at the same time, from the dangerous irritability to which starvation made it subject. Barley-water was the best food to give by the mouth after twenty-four hours. Meat-broths were not advisable before the bowels were opened, they tended to make the urine concentrated. Exclusive milk-diet was bad, but a certain amount of milk was beneficial after the second or third day. The bowels were best opened by drugs when there were signs of gastro-intestinal irritation; by enemata when the patient was doing well and it was simply a question of removing accumulated fæces. After a fair action of the bowels, fish, and then fowl, and then meat, might safely be given. Whenever sickness or flatulence returned or came on some days after abdominal section, it was best to stop feeding by the mouth and to rely on beef-tea enemata. The dangers of flatulent distension were very great whether the flatulence were primary or secondary, and feeding by the mouth increased those dangers.

Dr. **Travers** said the subject raised questions of considerable interest. He desired especially to say how much reliance he placed on turpentine in cases of flatulence.

Mr. **Jessett** preferred peptonised foods for rectal feeding, also alternation of fluids and suppositories; he considered flatulence chiefly due to paralysis of the bowel from handling.

Dr. **Macnaughton Jones** also had a high opinion of the value of turpentine in flatulence.

Mr. **Bidwell** thought solids might be given early; fish after the fourth day.

Mr. **Cheatle** read a paper on "Complications in Certain Diseases of the Middle Ear."

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Thursday, January 18th, 1894.

The President, Mr. **Richard Favell**, M.R.C.S., in the Chair.

SPECIMENS.

Dr. **Arthur Hall** showed microscopic specimens of adenoid cancer of rectum; also a liver with perihepatitis.

Dr. **Hunt** showed a specimen of cancer for which he had recently performed excision of the tongue.

Dr. **Waters** showed the uterus and lungs from an unusual case of puerperal fever.

Dr. **Burgess** showed a brain with fresh blood clots in the ventricles.

Mr. **Pye-Smith** showed a young man whose left eye had been penetrated a month previously by a chip of steel from a hammer with which he was striking. The chip had gone through the cornea, iris, and edge of lens on the inner side of the eye and had struck, and perhaps passed through the sclerotic at the equator on the inner side, where a white scar was visible. Vision was $^{10}/_{70}$

Mr. **Richard Favell** showed a multilocular ovarian tumour removed from a woman 2½ months after her confinement, 1st child. The tumour was felt after the expulsion of the child and placenta lying in the middle line above the pubes. The puerperal period ran a natural course, the tumour remaining inert and setting up no irritation.

Dr. **Sinclair White** related particulars of a case in which he had removed the vermiform appendix for relapsing appendicitis. The patient was a waitress, æt. 22. Her first attack occurred in December, 1892. During the succeeding four months she had three relapses, each of which appeared immediately on attempting to partake of solid food. She was operated on in May, 1893. The appendix was very much thickened, but measured only an inch in length. It was tightly stretched, and its apex adherent to a coil of the ileum deep in the pelvis. There were no concretions and no pus. Owing to its pelvic position it was impossible to feel the deformed appendix previous to operation. The patient made a good recovery, and had returned to her situation.

Mr. **Snell** introduced a boy, æt. 12, the interesting feature being the small field of vision; perimetric chart showed that it was confined almost to the point of fixation. It had existed for years, but the lad had nevertheless pursued very successfully his studies. Vision, $^{6}/_{18}$ in each eye, the discs were white and suggested antecedent neurites. There appeared to have been meningites in infancy. The case raised the interesting medico-legal point as to what could be done, not only in near work but in walking easily about with such a very restricted field.

Dr. **Porter** showed, for Mr. C. A. Atkin, specimens from a case of simple ulcerative colitis. The patient, a man, æt. 27, was ill for rather more than a month with profuse diarrhœa, offensive dark-brown motions mixed with bright fluid blood and clots. Towards the end a large ulcer formed at the anal aperture. Post-mortem: There was complete ulceration of the colon and rectum, the folds of the mucous membrane being swollen between the ulcers in polypoid masses and of a port wine colour. There was a small perforation in the cæcum near the valve which was closed by adherent omentum. All the other organs of the body were healthy.

◆

France.

(From our own Correspondent.)

Paris, Feb. 3rd.

A New Treatment of Phthisis.

M. **Lancereaux** read a paper at the last meeting of the Académie de Médecine on a new treatment of consumption by substances which produce in the organism succinic acid, such as raw meat, fats, benzoic acid, carrots, green vegetables, &c.

According to the author, this treatment provoked a notable improvement in nearly all the patients on whom it was tried. What is the action of succinic acid? Does it kill the microbe? M. Lancereaux thought that this agent had no action on the tuberculous matter containing the microbes, but thanks to its antiseptic properties it prevents the propagation of the bacilli.

Compression of the Phrenic Nerve.

Dr. Bidon, of Marseilles, had recently recourse to digital compression of the phrenic nerve in two cases of spasm of the glottis, imitating thus the treatment of Prof. Leloir, of Lille, for obstinate hiccough. The first case observed by M. Bidon was that of a young hysterical girl who, after a convulsive attack, was seized with spasm of the glottis so violent that her life was in danger.

The practitioner buried his index finger between the origins of the sterno-mastoid muscle, by which means the phrenic nerve was compressed. Almost immediately the patient began to breathe, and continuing the digital pressure for the space of one minute, all symptoms had disappeared. The spasm returned at intervals subsequently, but the same treatment proved to be efficient.

The second case was that of a man already suffering from ataxy. He was suddenly seized with a feeling of constriction of the larynx, and in a few seconds fell off into a semi-asphyxiated condition. The attacks occurred every ten minutes. Digital pressure of the phrenic nerve produced an immediate cessation of the spasm, but when the finger was removed it returned. However, by persisting in this treatment the man recovered completely.

These cases go to prove that the above treatment can be relied on in spasm of the glottis, but its action must be indirect, as the pressure nerve does not control the larynx.

Treatment of Pneumonia.

Pilocarpine in croup, scarlatina, and certain other affections has rendered good service, and has many partisans, but none more warm than Prof. Sziklai, who pretends that he can cure acute pneumonia in three days by this agent, administered by the mouth or by hypodermic injection at the very outset. He cites several cases which he treated in this way, and all turned out well. No unpleasant symptom was witnessed in any of those treated.

Subclavicular Glands.

The value of the presence of glands in the subclavicular region as a symptom in certain morbid affections of the viscera has been admitted very generally. To diagnose carcinoma of the stomach or the head of the pancreas is not always easy, and when glands are found in the left subclavicular space little doubt need be entertained as to the nature of the disease. M. Gaillard read a paper before the Société des Hopitaux on this subject, in which was dscribed the following case:—A woman, æt. 63, came under his care at the hospital. She was in a very emaciated condition, presenting all the appearances of a person in the last stage of consumption. However, a very minute examination of the chest was unable to reveal any trace of tuberculosis. But in the left subclavicular space a lymphatic ganglion could be felt about the size of a marble, and close by two or three very small ganglions. On the right side nothing could be found. The microscopic examination of the expectoration failing to reveal the bacilli of Koch, M. Gaillard thought of the possibility of the existence of visceral cancer. A short time afterwards the woman died from broncho-pneumonia, and at the autopsy a small white mass was discovered in the region of the thymus gland, which was proved to be cancerous. No trace of cancer was found elsewhere.

◆

Germany.

[From our own Correspondent.]

Berlin, Feb. 2nd.

Medical Statistics in Berlin.

The week before last I referred to Dr. Weyl's paper on "Medical Statistics" read before the Medical Society, in which it was claimed that the diminution in the death-rate that has taken place during the past few years was due to an improved water supply and to improvements in the system of drainage. After the proceedings connected with the annual meeting, the Society proceeded to discuss the paper, when somewhat of a surprise was experienced.

Dr. Zadek, who has recently come rapidly to the front as a leader of the Social Democrats, and who is one of the City Deputies, denied that the diminished death-rate could properly be placed to the credit of either the water supply or to any system of sewage. He maintained that Dr. Weyl had left out of his calculation the chief cause of the diminished death-rate. This, he claimed, lay in *the diminished birth-rate* in Berlin. The fewer children were born, the fewer died, and the mortality amongst infants was always the most important part of the total mortality. The increase in the population of the city was not due to births in the city, but principally to the influx of grown-up people mostly at the best age—between twenty and thirty. The increased population being brought about in this way in conjunction with the diminished birth-rate sufficiently explained the diminished death-rate. It was not necessary to invoke the aid of hygienic causes to explain the facts. At the most a diminished death-rate in infants might be assisted by improvement in the milk supply, but the city of Berlin had done nothing to diminish the shockingly high infant mortality; it had done nothing to assist poor lying-in women, nor for foundlings; it had done nothing to prevent overcrowding of the dwellings of the poor, and had refused to supply sterilised milk for the children of the poor. It was not entitled to the credit of the diminished mortality from diarrhœa, tetanus, &c. Consumption had diminished in the city only because of the influx of more resisting older classes of people from without.

On the other hand, he entirely agreed with the proposed hygienic demands of Hr. Werzl. As a member of the City Council he had already made proposals for the introduction of school physicians and health overseers, for the better cleansing of school rooms, for gratis disinfection, for improvement in the treatment of convalescents, for the re-arrangement of medical services in the city hospitals, &c. All his exertions, however, for lack of understanding had remained unconsidered.

This reverse side of the medal, the condemnation of the otherwise so much lauded hygienic condition of the city made, we are told, a deep impression, and the conclusion of his speech met with considerable applause.

Transmission of Tubercle through the Placenta.

At the same meeting Hr. Lehmann showed preparations presenting the typical appearances of placental tuberculosis, taken from a patient suffering from tubercle of the lungs and larynx. The patient was confined on December 1st, 1893, and was still in hospital under treatment for the disease. The tuberculous tissue changes were present in the chorionic tufts. The child died on the tenth day, but without presenting on post-mortem examination any appearances due to tubercle. The transmigration of the disease from the chorion to the glands and bones as the natural and continuous channel was certainly presumable. He suspected that by such observations one would be led back once more to the older views. In the preparations the tuberculous nodules were grey, translucent, and round. It was to be presumed theoretically that the tubercle first developed in the decidua; the further passage to the chorion was then readily explained by the breaking through of tuberculous centres.

At the meeting of the Society for Innere Medizin Hr. Ullmann reported a case of

Membranous Enteritis.

The preparation was taken from a child born of a healthy mother on September 29th of last year. The child was perfectly quiet the first day; in the afternoon a something that looked like a young cucumber was found in the napkin. It was 2·5 cm. in diameter at one end and 1·5 at the other, and 7 cm. long, coloured a dark green in the centre and a yellowish green at the ends. One end was pedunculated and twisted. It had a thready mucous covering. It consisted of dark green contents with a smooth skin. The contents were meconium. The dark green colour of the skin was due to imbibition of biliary colouring matter. There was also a stringy structure with a skin of several layers lying together. The striated arrangement arose from the embedded cells running lengthwise in each layer. It was evident that the sausage-shaped object came from the ampullæ of the rectum. It was clear that it was formed a considerable time before birth.

Hr. Rothmann had also seen a case of true membranous enteritis in a new-born child. Fæcal vomiting came on soon after the birth of the child. After injection into the bowel meconium was passed in balls covered with mucus. Four hours later, after taking food, fæces were passed per os. As the child did not improve under treatment it was taken into hospital, when an artificial anus was made. It died on the twelfth day, passing two days before its death a true membrane as in enteritis. On post-mortem examination intussusception was found in the lower portion of the ileum. The colon was completely collapsed; there were numerous pieces of membrane in the large intestine.

A Windfall for Berlin University.

From a legacy of 100,000 marks under the will of Dr.

Adolf Düsterhoff, just received by the authorities, the most diligent student of medicine in the University will receive each six months the interest of this trust fund to help him in his studies. The amount available for this purpose is calculated at about £200 per annum.

Vienna, Feb. 2nd.

Sub-Conjunctival Injections.

Prof. Bergmeister related his experience with not a little confidence in the success attending sub-conjunctival injections of sublimate in ocular afflictions. He assured the "Aerzte" that this was no new treatment for Darier is reported to have practised it in 1889, and since then it had frequently been tried in France. There was little doubt of its efficacy in the infectious diseases. In these cases it is not advisable to use strong antiseptics for the bulbus, for mercury when injected into the vitreous humour produces violent phenomena. His own practice was to use a "Pravaz" syringe armed with a steel needle having a gold cannula and a mercurial solution of 1 in 2,000, of which he injected 3 to 4 minims under the conjunctiva at the margin of the cornea after the eye had been well cocainised to reduce the pain. After the injection the whole surface becomes chemotic, becoming more intense during the next half hour, but not causing any great amount of pain.

At this point he showed a young woman in whom he had performed iridocyclitis, but which threatened speedy destruction in spite of anti-syphilitic treatment, but which yielded immediately after four injections of the mercury.

Two other cases, one of which was a woman, æt. 68, with recently acquired syphilis and specific iritis of the left eye. After three sub-conjunctival injections of sublimate, no other medicine being given, the eye rapidly healed. By experimental injections this sublimate was found twelve hours later in the anterior chamber, and operated as an antiseptic notwithstanding the small quantity injected.

Prof. Reuss remarked that he had frequently used this method of treatment in his own section. He quite agreed with Bergmeister that it was efficacious and easily applied even without the aid of assistance, though he could not boast of a golden cannula in his case, but he had used the cyanate of mercury with equal effect. Bergmeister added that he had attempted to carry this local treatment further in other diseases, but doubted their success. He had applied injections of three per cent. salicylate of soda solutions in rheumatic scleritis, but with very questionable results.

Iodide Œdema.

At the "Doktoren Kollegiums" Ziesl related the results of his experiments with the iodide of potassium which he has performed in Basch's laboratory. He confined his investigations to subcutaneous injections of the iodine preparations to dogs. When injected into the vena jugularis a severe œdema of the lung ensued, which is rapidly induced by the use of iodo-iodate of soda. The iodate of potassium and lithia do not exhibit these phenomena. The œdema has every appearance of muscarine action. These experiments perfectly accord with the clinical observations recently observed in the human subject, where large quantities of iodoform had been brought into contact with open wounds and sudden death from œdema of the lung being proved at the post-mortem.

Prof. Basch remarked that he had watched several of these experiments, and quite concurred in the results drawn from the phenomena. He considered the heart was in a certain measure influenced by the drug, that the flow of blood in the lung was retarded, and that hyperæmia with œdema and apoplexy was the result, thus producing dyspnœa as the result of transudation. These, he presumed, were important points to be noted in the use of iodine, as he considered the accidents due to it more common than was usually admitted. This condition of the lung obtains with equal significance as muscarine and other mechanical irritations, though he must admit the use of iodine was more severe than any of them. The next question to be investigated was whether the blood or the vessels were at fault. Should it turn out that the changes were confined to the vessels and the transudation resulting therefrom it would go far to prove the arterio-sclerosis of syphilis which is often found in those subjects at death after long treatment with the drug.

The Operating Theatres.

ROYAL FREE HOSPITAL.

Radical Cure of Hydrocele.—Unusual Condition of Sac.—Mr. **Battle** operated on a young man, æt. 18, who had been rejected on application for enlistment in the army, on account of a swelling in the right side of the scrotum. The patient had not paid much attention to the swelling himself until it had been pointed out to him by the examining officer. It had caused him no pain or inconvenience. The right side of the scrotum was moderately distended with a soft, fluctuating, translucent, cylindrical swelling, which extended into the inguinal canal, but there was no impulse on coughing, nor could the swelling be reduced with gentle taxis. Under an anæsthetic, however, Mr. Battle pointed out that the swelling could be partially reduced into the abdomen, but that it required steady and firm pressure to effect this. He proposed at first to treat the hydrocele by means of Volckman's method, but on finding the fluid could be returned to the abdomen he decided to treat it as a case of empty congenital hernial sac. Accordingly an incision was made into the sac and the hydrocele emptied. On passing the finger along the canal no opening could be felt through which the fluid had been expressed before operation; it simply entered a *cul-de-sac*; more prolonged examination showed that this condition of the sac resulted from the presence of a valve-like fold of peritoneum with a thickened edge concave towards the testis and situated below the internal ring; this, when opposed to the posterior and opposite wall, effectually prevented the escape of fluid until considerable pressure had caused the sac to dilate at the neck, when the free margin of the cusp was lifted from the part against which it had previously rested; the sac near this valve was somewhat white in patches and thickened. A tunica vaginalis was fashioned by dividing the sac across about half an inch above the level of the epididymis, and the insertion of a continuous suture in the lower part; the upper part was carefully dissected up from the cord, to which it was rather adherent, and was difficult of separation on account of its thinness; a silk ligature was applied round the neck of the sac at a level of the internal ring and the wound afterwards closed, a drainage tube being inserted. Mr. Battle pointed out that he did not suture the pillars of the ring because, although the finger could be passed through into the abdomen, the internal ring was valve-shaped and did not appear to have been distended or stretched by any hernial protrusion; he also said that the condition of valve was rare and that he had only met with it in on one former occasion, and that was in the case of a young naval officer on whom he had operated for radical cure of an irreducible inguinal hernia; he had found when operating that the hernia was irreducible on account of a pouch into which the omentum passed; it was of similar formation to the one in the present case. He considered that in both cases the pouch had been formed by an imperfect attempt at closure of the funicular process of the peritoneum. He showed the structure of the abdominal opening was such that an attempt to expel any of the abdominal contents would force the flaps of this valve together and so close the opening. He thought that in cases similar to this it was possible to obtain a radical cure of a hernia without suturing the pillars of the ring, but that such cases were rarely met with.

GREAT NORTHERN HOSPITAL.

Laminectomy.—The patient operated upon by Mr. **Herbert Allingham** was a girl, æt. 18, who had had a dorsal angular curvature for the last two years. About a month back she lost all power in her legs and bladder; this was soon followed by absolute loss of sensation also, and large sloughs formed over the sacrum and heels. On admission a large curve was noticed in the spine above the upper dorsal region. There was complete paralysis and loss of sensation up to the umbilicus, no power over bladder and rectum, and large sloughs upon the heels and sacrum. Patient very ill and temperature high. Mr. Allingham made an incision over the spinal prominence about 7 inches long, freed the muscles from the spinous processes, cut them away and sawed through the laminæ, removing the laminæ of about three vertebræ. The cord was exposed and found to have been pressed upon by one of the laminæ. The dura mater of the cord was opened. No abscess was found. It is interesting to note that four days after the operation the sensation in the legs had returned, and that the patient had recovered some power over the bladder, and that she is daily improving.

The four boys and the servant who a few weeks ago were sent to the Pasteur Institute in Paris for treatment after having been bitten by a mad dog at Wavertree have arrived home. Each of them were inoculated twice daily for the first five days after their arrival, and afterwards once daily for ten days. No bad symptoms have so far developed.

An experienced Medical Officer of Prisons has said that sick convicts reminded him of the lower animals by the uncomplaining, patient way in which they passed through severe illnesses.

A criminal lawyer of Cincinnati boasts that he is able at a glance to tell a criminal from an innocent person. Clearly this is just the kind of man required for lynch-law practice.

Dr. Latham has resigned the Downing Professorship of Medicine in the University of Cambridge, after having held the post for twenty years.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 7, 1894.

THE LEGAL PERILS OF MEDICAL MEN.

In the Annual Report of the Medical Defence Union for 1893, just issued, some interesting details are contained with reference to the cases defended or otherwise dealt with by the Union. It is worthy of note that the applications of the members for protection were of the most varied description, indeed, many of these were outside the powers and province of the Union, by reason of the fact that no question of professional principle was involved. For example, one member applied for assistance to defend an action brought against him by the friends of a patient by whose will he had become entitled to £12,000! The friends were about to contest the will, and the member thought that the Union might help him, but the application was rejected. Another similar case was that of a member who was threatened with action for injuries resulting from his bicycle causing a person's horse to bolt. But here again, of course, the application for assistance was not within the province of the Union. Among the more serious cases with which the Union had to deal may be mentioned the following: A hospital ophthalmic surgeon who was a member performed a preliminary iridectomy for cataract. The operation was, as far as its details went, perfectly successful, but panopthalmitis ensued, requiring enucleation of the globe. The member received a letter from the patient demanding compensation and threatening, in the alternative, an action at law. The letter was replied to by the secretaries of the Union, stating that the solicitors of the Union were prepared to accept service on behalf of the attacked member. This led to the collapse of the case. Again, a woman who had formerly been a patient of a member received in due course a request for payment of his professional charges. Her reply, however, was a threat to bring proceedings of affiliation. This she did, and the medical man was defended by the Union. The case was dismissed by the magistrate, on the ground of the entire absence of corroborative evidence. In both these cases it is plain that the Union rendered signal services to the members who had appealed for assistance, and the same may be said of the member against whom a patient made an accusation of criminal assault, demanding £500 damages. In this instance the secretaries wrote demanding a retraction and an apology, with the result that the request was immediately complied with. As showing the importance of the Union to medical practitioners attending cases of midwifery two cases may be cited. In one a patient died from puerperal fever, and the medical man was threatened with an action for negligent treatment, and in the other the action was threatened on account of alleged malpraxis, by which secondary post-partum hæmorrhage ensued. In each case the Union informed the plaintiff that its solicitors would accept service on behalf of the medical man concerned, and the result of this was that both cases at once collapsed. In a large number of cases advice was given to members who complained of improper criticism on the part of patients, clergymen and other persons. In numerous cases the secretaries have addressed letters of warning to persons known to be circulating slanderous reports concerning members, and this course not unfrequently caused the annoyance to cease. Included, also, among the list of cases for last year is the action for libel by the Medical Battery Company, based on a letter addressed by Dr. Bateman to the medical journals. Dr. Bateman, on behalf of the Union, defended this action, and in the end it was withdrawn by the plaintiff, who paid all costs. Practitioners, it seems, are exposed to legal proceedings for quite unexpected reasons. For example, a member of the Union was threatened with an action by a person who alleged negligence in the non-diagnosis of a case of scarlet fever. But this person thought better of his contemplated proceedings when the Union gave instructions that it would defend the action. The case collapsed. From these brief references it will at once appear plain how important it is for medical men to belong to such an association as that under discussion. At any moment they might require its valuable aid, and it is highly gratifying to note that in many instances nothing more than the intimation of the intention to defend an action was sufficient to cause the collapse of the case.

PRISONS AND PRISONERS.

One of the most remarkable phases of the "new journalism" is the boldness with which it criticises the conduct and the ultimate results of each and every department of State administration. Nor is this tendency to be deprecated, for it may be safely asserted that this country, the freest in the world, owes no small measure of that freedom to the outspoken energy of an independent press. So that the modern mind has become familiar with the process of an agitation started by the public newspapers, sifted by official Government inquiry, and followed by legislative reforms. Quite lately a lay contemporary has cast the journalistic searchlight upon what appears to constitute a dark spot in our social system. Its special commissioner has contributed a series of articles animadverting seriously upon the defects of our prison system. He characterises as a failure the present method of administration which is carried on under the Home Office and Sir Edmund Du Cane. He condemns unsparingly the militarism and bureaucracy of the central control which is virtually placed in the hands of Sir Edmund, and these defects he attributes to the increased powers vested in the Prisons Board by Disraeli's Act of 1877. Speaking of "solitary confinement," he writes: "I am for rigid separation at night and for associated work in the daytime, the kind of work indeed which went on in the prisons very much more largely than since the full establishment of the Du Cane *régime*, with its cheeseparings and its increasing rigors. Without any extension of the workshop system the curse of the solitary system cannot be abated, and I would rather the Home Secretary did not touch the matter at all unless he declares for associated work instead of for 23 hours in the cell." From these sentences readers will readily infer that the commissioner is a man of strong views and energetic language. As to the truth of his assertions it is not our business to inquire, that is a task which may safely be left to others, but there are some more purely medical aspects of the case to which the attention of scientists, whether anthropologists, alienists, or sociologists, may be drawn with advantage. But in the first place it will be well to glance at the admitted evils of the cellular system, with its terrible silence, its lack of human interests, its monotony, and its utter erasure of sympathy. No scheme for the regulation of society that has yet been proposed has, so far as we know, definitely asserted that all crime should be treated as a symptom of a pathological moral state. Even the most advanced psychologists do not appear to have imagined such a position as falling within the range of practical jurisdiction. But apart from such abstract questions there is no doubt that only too often as the outcome of modern punishment the spirit of the criminal is broken and his self-respect destroyed. The very fact that he is cut off from all useful work is in itself a degradation and an ever-present reproach. Indeed, there is no question that our prison system has not justified the contentions of those who were answerable for its initiation. There is probably some truth in the complaint that the official staff is both overworked and undermanned. The fact of the increasing percentage of re-committals during late years certainly points to the bad moral influence of solitary confinement upon prisoners. Between 1857 and 1876 the re-committals average 34 per cent. Between 1888 and 1892, under the new system, they rose to 48 per cent. All these statements are sufficiently suggestive to demand a searching inquiry, but there are other aspects of the question with which medical men are more directly concerned. It is freely alleged that the prison fare is such that the health of the unfortunate criminal is often seriously undermined, or more particularly, that the food is inferior both in quality and quantity, and is, indeed, barely sufficient to maintain life. If these accusations be true, then there is urgent need of drastic reform. Our criminal population is already large, and its recruits appear to be drawn chiefly from those waifs and strays of society, discharged prisoners. In other words, if current criticisms be correct, the modern system turns out men who have served their sentences in such a condition of mental and bodily starvation that their speedy relapse into criminal courses is well nigh an absolute certainty. This state of affairs, if only partially true, deserves the serious attention of scientific men. By all means let physiologists, physicians, and alienists go to work and settle authoritatively once for all whether the food and the surroundings of the modern prisoner are or are not such as to undermine his physical and mental life, and so render him an ever-increasing danger to the welfare of the community.

Notes on Current Topics.

Latin and Medicine.

THE struggle between the classical and the scientific methods of education which from time to time goes through an acute stage in this country is just now the order of the day in French educational circles, so far as medical students are concerned. Dr. Potain recently made a report to the Minister of Public Instruction in which he vehemently opposed the proposal to admit to the study of medicine men who had matriculated on the "modern" side. All the old saws about the elevating and refining virtues of a classical education were re-edited on this occasion, but Dr. Potain, like so many others on this side of the Channel, forgets that this train of reasoning is altogether *ultra vires.* No educated person would deny for an instant, or in any degree, the advantages attending a thorough acquaintance with ancient literature, but this does not imply that it is indispensable to the formation of a sound practitioner or an astute and successful lawyer. We have consistently taken the view that while very desirable, a knowledge of Latin and *a fortiori* of Greek, ought not to be exacted of all candidates irrespective of their personal tastes and aptitudes. The ancient languages cannot be considered to be indispensable to a medical training even in respect of terminology, for this can be mastered by an effort of the memory, and it would be easy and profitable to substitute modern languages and a more perfect acquaintance with sciences germane to medicine. Medicine is before everything a science of observation, and no course of training is so conducive to exact observation and logical deduction as the scientific. This is not a new view, for the absurd importance attached by the orthodox physician was ridiculed by Rabelais and later by Molière. Medical men have gained in status and medical science in precision since the days of Molière, but we must beware lest, by too fervid and persistent a prejudice in favour of Latin, to the exclusion of other more immediately important subjects, we create an impression among the outside and irreverent public that if medicine has advanced medical men are fundamentally the same. We are glad to hear that a movement is on foot in England in favour of writing all prescriptions in the vernacular—a practice which long since became general in France. If the modern school in France succeed in carrying their point, the bigwigs of the Faculty notwithstanding, a great step will have been taken in the direction of rendering the training of medical students more purely scientific. The present standard of attainments required in Latin here, as there, is miserably inadequate, and does not confer upon those who have attained it any of the advantages claimed for a sound classical education. The standard cannot well be raised, because the requirements in respect of the sciences are yearly being rendered more stringent. The time misspent in acquiring this mere smattering of the classics had, therefore, far better be spent in a more useful field of labour.

A Medical Trading Company, Limited.

THIS is a progressive age, and one must be prepared for surprises; but by this time probably most of our readers will have seen an announcement of the formation of a Medical Trading Company which must have fairly astounded them. For sheer audacity and impertinence the announcement in question surpasses anything of the kind which has come under our notice. On the 24th ult. a new company was registered under the style of "The New Premier Medical Aid and Insurance Association, Limited," with a capital of £50,000 in £1 shares. The objects of this company are stated to be "to provide medical and surgical attendance and medicine and surgical appliances, generally to carry on the business of a Medical Aid Association and Agency, to appoint and dismiss such medical and other officers, servants, clerks, and agents as may be necessary, and to pay them by fees, salary, commission or otherwise, and to carry on business as insurance, guarantee, and indemnity in every branch saving that of life insurance and life annuity business." Then follow the names of seven persons, with their addresses, forming the signatories, and the interesting details are added that there shall not be less than three nor more than seven directors. The first are to be appointed by the signatories to the memorandum of association; qualification, £100 shares or stock; remuneration, £300 per annum, and a percentage of the profits divided between them. Let the profession read, mark, learn, and inwardly digest this latest phase of the prostituting process which has been introduced by these Medical Aid Associations. There is one question in this connection to which the profession must insist upon an answer. Has the General Medical Council absolutely determined to take no further steps in putting a stop to medical men connecting themselves with these wholly unprofessional concerns? The whole of the matter has been laid before it in a manner which fully proved the objectionable nature in a professional respect of the work of these associations. But the timid policy of the Council resulted in a resolution which was practically meaningless, and which experience has shown to be entirely inoperative. If the General Medical Council will not protect the profession, then the profession must take steps to protect itself. To discuss, however, at all dispassionately this latest scheme for trading by means of medical men is scarcely possible. On the face of it it is insulting to a degree, and it may be safely predicted that in the event of the company paying good dividends, similar schemes of the kind will be founded all over the country. Verily the profession has a great deal to thank the General Medical Council for in this matter!

The Erectile Tissues.

Dr. Caldwell, of Baltimore, sends us a paper under this heading in which he groups the causes, symptoms, and treatment of impotence and sterility in both sexes. The old theory of the existence of "nervi erigentes," by whose action alone such tissues were swelled, has now given place to the more rational idea of a genito-spinal centre governing certain muscular bands which can compress the veins and impede the outflow of blood from the tract. It is, therefore, worth remembering that the relations between potency and the vasomotor tonus of the genito-spinal centre are very close. Among the ordinary causes of impotence Dr. Caldwell classes and lays some stress on the over use of both tobacco and alcohol, giving an instance of a case belonging to the former category. Remarkable success seems to have attended the author in his endeavours in some cases to facilitate the appearance of the long-waited for hair, although to our ears, apart from the usual tonic treatment adopted and holidays advised, the list of drugs recommended as useful in such contingencies sounds somewhat strange. Here are some of them:—Damiana, yerba santa, saw palmetto, vanilla, black haw, picki, and stylo-santhus elatior. We concur in his remarks on the danger to the community to be found in the large trade obtained by advertising quacks in these delicate and often all-important cases. It would be well if the advertisements of such men could be forbidden.

Phonographic Otitis.

A new competitor for public patronage has made his appearance during the last year or so at the street corners and unoccupied shops. He is the proud possessor of a diminutive machine provided with octopus-like prolongations which hang down gracefully along its sides and ends, and its very appearance is calculated to rivet the attention of the passer-by. This is the latest form of Edison's wonderful phonograph, which, after having for years been seen little of outside scientific societies and evening parties, has now been popularised on a large scale. It cannot be denied that the entertainment is well worth the price charged per *séance*. One has only to push the xylonite extremities well into the ears, and then on touching a spring one is treated to band music, orations, humorous recitals, and the whole, or part, of a very extensive *répertoire*, as per contract. As a means of educating and amusing the public nothing could be better, but every medal has its reverse, and the phonograph is not exempt from the common failing. Our attention was called to this "reverse" by several cases in which patients with catarrh and even suppuration of the external ear have dated the onset of the affection from their interview with the aforesaid phonograph. One hardly needs a medical education to appreciate at once the gravity of the risks incurred by pushing into one's ears a nozzle which has been used by a motley crowd, possibly only a few instants previously. When one reflects upon the very large proportion of people who suffer from one form or another of suppurative disease the danger, nay the certainty, of the transfer of the *materies morbi* is apparent. In many cases the matter thus introduced into so sensitive an organ as the ear is of such a virulent nature that no special predisposition is necessary on the part of the recipient to ensure immediate irritation, followed in all probability by more or less serious local mischief. Every medical man is cognisant of the risks entailed by suppurative disease of the ear. So grave is it, even in comparatively mild cases, that life assurance companies usually hesitate to accept a proposal from anyone thus afflicted. Hence it is sufficient to call attention to the danger to ensure that intelligent persons will think twice before listening to a public phonograph, though for the matter of that the risk is not materially less when the exhibition takes place in a drawing-room instead of at a street-corner.

The Extension of St. Bartholomew's Hospital.

The Governors of St. Bartholomew's Hospital have in contemplation the proposal to purchase some of the land which will be available for building purposes after the boys at Christ's Hospital have found a home in the country. It has for long been felt that some extension of St. Bartholomew's was urgently needed. In the first place the present out-patient department is totally inadequate for the purposes of the requirements of the work entailed by the crowds of out-patients which throng for treatment. Again, anyone who knows St. Bartholomew's must admit that the present college for the students is unworthy of the great medical school. Possibly in earlier days the college served its purpose, but now competition has come into play, and other hospitals have shown the students what a residential college should be, and how far that at St. Bartholomew's is behind the requirements of the times. Lastly, new quarters are urgently needed for the resident medical staff, as well as for the nurses. Evidently, therefore, the Governors of the hospital have no option in coming to a decision in respect to the purchase of land for extension purposes.

Alleged Asylums Board Extravagance.

It is usual with a certain class of writers who favour the principle of democratic local administration to point to the London Asylums Board as a striking instance of the success of a decentralising system. That the work of the Board is well done most people will readily admit. Its lunatic asylums are well regulated, properly constructed, and for the most part fulfil the requirements of modern scientific treatment. On the other hand, its fever hospitals are insufficient in number, and now and then one hears a hint that their internal economy might bear an occasional overhaul with advantage. Of late the Board has advanced a scheme which has startled Boards of Guardians all over the metropolis by its costliness, and at numerous vestry meetings the attention of members has been called to what has been freely described as the extravagance of the Asylums Board. Nor does the latter description appear to be altogether unwarranted by the facts of the case. Briefly, the Asylums Board proposes to build a new hospital at Shooter's Hill at a cost of £220,000, or £440 a bed. That sum certainly seems unduly large, especially when it is stated that it does not include the purchase of land and of pumping machinery. At the same time it must be remembered that the Local Government now exacts a much larger air space for patients than formerly, so that larger wards are needed. There is another item in the scheme for the new hospital which will require a good deal of explanation, namely, that beds have been provided for 300 officers to wait on the 500 patients. The statement that this large staff is wanted because of the increase of diphtheria patients does not appear to us to afford an adequate reason for such a proportion as three officers to one patient. The contrast from some recent revelations as the scandalous under-nursing of some of our Poor-law infirmaries is simply startling. The attention of the Local Government Board might be directed with advantage to the double task of stirring up the penurious no less than of checking the extravagant Boards.

The Prosecution of Qualified Unregistered Practitioners.

A case of some importance came before the magistrate at Greenwich Police Court last week. A practitioner was summoned by the Superintendent Registrar of Births and Deaths for the district for wilfully making a false certificate respecting the death of a child. The evidence showed that the practitioner in question was an assistant to another medical man and held the diploma of "L.R.C.P.," and the offence was that he signed the death certificate as if he were registered under this qualification. As a matter of fact, however, he was not registered, inasmuch as since 1887 a double qualification in medicine and surgery has been requisite before registration was obtainable. The Superintendent admitted that there were medical men holding good medical appointments with only the same qualification as that possessed by the defendant, but this fact did not alter the circumstances of the present case. A fine of twenty shillings and two shillings costs was imposed. Legally, of course, the practitioner was in error in representing himself as registered when he was not so, but presumably he could have overcome the difficulty while filling in the death certificate either by erasing the word "registered" or by inserting the letters "un" before it. Strictly speaking the offence was one of a technical nature rather than one which really called for the active steps taken by the Superintendent Registrar for the purpose of vindicating the law. We should have supposed that a timely warning from this official to the practitioner to the effect that the latter could not be allowed to represent himself as registered would have amply met the circumstances of the case. Had the false representation not been made the Superintendent could not have proceeded against the practitioner for filling in the certificate.

A Hint for Dublin Educational Authorities.

We invite the very serious attention of Dublin teachers and colleges to the list of Irish students published by the Scotch Examining Board in the medical and other papers. Thirty students who, one would think, ought to be the legitimate "spoil" of the Dublin Colleges, are gazetted as having passed their exams. in Scotland. Why? Is it because one or other of the Dublin Colleges is so inflated with the sense of its own supreme respectability that it cannot descend to do business in a practical way? or is it that the Colleges are too busy squabbling with each other to give attention to the wholesale exodus of Irish students? Or is it that Dublin teachers and Dublin Colleges are willing to pile on additional fees for the teaching of such redundant specialities as mental disease and vaccination? or is it that the Dublin diploma fee of £42 is kept up to a prohibitory amount because the dignity of somebody will not come down to market price? or, (we think not) that Dublin teaching is less thorough, less businesslike, less carefully supervised, and less attractive to students than elsewhere? or is it that the Irish examinations are more "cruxy," more like a collecting of examinations in specialities, less calculated to test what the practical knowledge of the student is, or more risky in the passing? We cannot answer. But we are quite clear that the sooner the Dublin teachers and qualifying bodies proceed to set their heads together to solve the riddle like sensible men the better for their prospects.

Dr. Cornelius Herz.

Dr. Cornelius Herz has a serious grievance against the French medical men who were deputed by their Government to examine and report upon his case. According to his statement they never made any physical examination of him, although it was known that he was suffering from heart disease, and while admitting that he was ill, they agreed that he could not be taken to Bow Street without putting his life in danger. Yet, despite all this, on their return to Paris they affirmed that Dr. Herz was well enough to be extradited. Clearly either Dr. Herz has been very ill-used in the matter or he is mistaken in his facts.

Fraudulent Titles.

A case came before the Houghton (Durham) magistrates on Thursday last which revealed the practice of fraud on the public almost inconceivable in its barefaced audacity. Eighteen months ago the *soi-disant* doctor was a working miner, but being desirous of soaring in higher elements he was elected member of "The Incorporated Council of Safe Medicine," and forthwith set up in practice with a brass-plate on his door with the magic initials M.D., B.C., after his name. He visited and prescribed, signed death and birth certificates, and even notified cases of infectious disease under the Act to the Medical Officer of Health. Neither his brazen face nor door-plate, however, will now avail him, and the heavy fine inflicted with the alternative of imprisonment may perhaps teach him that, although the public may be hoodwinked with fraudulent titles for a time, a day of reckoning is a certain eventuality. During the hearing it was sought to fix the initial prosecution on the Medical Officer of Health; he, however, proved that he had ignored the fellow altogether. But what of this iniquity, "The Society of Safe Medicine," which awarded the miner a diploma and elected him member of the Council? Need we add that this is of American origin, and like all this class of quackery, is helped in its unholy work by ministers of various religious denominations, which our laws are impotent to arrest.

No Money Returned!

It is unfortunately not unusual for a doctor to have to sue for a fee, but we never, until now, heard of a case in which a doctor was sued for the recovery of part of a fee which had already been voluntarily paid to him. Such a case was tried before the County Court Judge for Fermanagh last week. Drs. Walsh and Gunning, of Enniskillen, had been summoned to to attend a farmer's son who had received a very dangerous injury of the thigh. They had to drive ten miles in the middle of the night, and to walk a mile up the mountain. They found that amputation was indispensable, and told the farmer the boy could be operated on in the County Infirmary at a small charge, but that they considered that his removal to such a distance would be excessively dangerous. The farmer elected to pay the requisite fees, which he was apparently well able to do, and the amputation was then and there done. The doctors did not leave the house until three o'clock the next day, when their fees (£10 to Dr. Walsh, and £5 to Dr. Gunning) were cheerfully paid. The boy subsequently died from secondary hæmorrhage, and the farmer now sued Dr. Gunning to get back £2 18s. We do not know by what principle of law or equity such a claim could be upheld. At all events, the Judge at once dismissed the case with costs against the farmer.

The Bengal Branch of the Pasteur Institute was successfully inaugurated on the 30th ult. in the presence of a large company. After the ceremony subscriptions to a considerable amount were promised.

The Signs of Death.

The only certain evidence upon which reliance can be placed of death having occurred is the presence of decomposition. In this connection a curious experience recently came under the notice of a medical man in respect to a patient who had died from angina pectoris. The report runs that "the face of the corpse seemed to be bathed in perspiration, the moisture reproducing itself after having been repeatedly wiped off, despite the presence of *rigor mortis* and other unmistakable evidences of death. This most extraordinary phenomenon was witnessed by several local medical men who also viewed the body. The funeral was consequently delayed several hours until decomposition had fully set in." Doubtless certain physical causes were present to account for the phenomenon displayed, but it would be difficult to explain precisely their true nature. Obviously, however, in all cases of suspected so-called suspended animation the duty of the medical man is clearly defined. He should prohibit the ceremony of burial until the unequivocal signs of decomposition have developed.

The Coombe Lying-in Hospital.

We understand that the Council of the Dublin Hospital Sunday Fund decided at its meeting on Wednesday last to withhold the grant to the Coombe Hospital until the Committee of Distribution should consider the administration of the hospital worthy of support. The amount of the grant would have been about £83. We believe that the Council, in coming to this conclusion, was influenced by the conduct of the Governors referred to in our last issue in refusing to appoint a Matron unless she was of their own religious persuasion. The suit of the late Master, Dr. Colclough-Hoey, for damages for libel against the *Irish Independent* seems to be still pending, for a preliminary motion in it was made in the Dublin law courts last week. If it goes to trial it is very certain that the public will know more about what are called the "Coombe Hospital Scandals" than they have yet had any opportunity of knowing.

The Harness Prosecution.

The magistrate at Marlborough Street Police-court last week stopped the proceedings in the Harness case, and the defendants were discharged. This result has come in no way as a surprise to those who had followed the course of the trial. The charges were of conspiracy to defraud, and the prosecution sought to infer the guilt of the defendants from their practice of demanding sums of money in advance and from their reluctance to fight out in open court charges previously brought against them. In order to do this successfully it became necessary to show that the defendants were absolutely cognisant of the fact that their electropathic belts were worthless appliances, and that the only way of securing payment for them was by demanding it beforehand. After hearing the evidence of the witnesses Mr. Hannay considered that the prosecution had failed to establish their case, and accordingly dismissed the defendants.

Travelling to the International Congress at Rome.

THE facilities afforded to members of the Congress by the home and Continental railways and steamship companies are most generous, and they indicate the anxiety of foreign nations to promote educational movements which are both financially and in other ways for the benefit of their countries. One great English Company, the London and North-Western, has distinguished itself, as, indeed, in many instances it has done before, for its stupid policy of selfishness. It has not been able to see that it would be to its own advantage to encourage doctors to go to Rome and to bring their wives and families, even though a minimum profit might be derived from the transaction. This is the system of administration which has caused the Company to fall back, as it has done, into the rear rank of the great English Companies, and which, if persisted in, will inevitably bring down the dividends and the prices of North-Western stock below the very modest value at which they now stand.

A New Phase in Milk Adulteration.

FOR a long time past a large trade has been done in adulterated milk by a person trading under the title of a Dairy Company. Numerous prosecutions and convictions have followed, and the "Company" has now hit on an ingenious plan for evading the Adulteration Acts. Their plan is to sell their milk to carriers, who also hire their barrows. The consequence is that when an inspector proves a case of adulteration he finds himself obliged to prosecute a man of straw. In a case which came before the Westminster Police Court a short while since, the defendant, a carrier, deposed that he paid 2s. a barn gallon for new milk and 1s. 1d. for skimmed, and 1s. 6d. a week for the hire of the Company's barrows. The prosecuting counsel observed that, although he had no moral doubt that the defendant in the case was sent out by the dealer, yet it could not be proved unless the former would give information. It is obvious that the interests of the public demand a legislative safeguard against an evasion of this kind.

The New Medical Officer of Health for Manchester.

THE Manchester City Council had not far to go in order to find a suitable candidate for the vacant post of Medical Officer of Health for the city. The appointment has been conferred upon Dr. James Niven, who for some years has been the Medical Officer of Health for Oldham. Thus, as has often proved to be the case in the competition for posts, the claims of a good local candidate have been shown to have been paramount. There were thirty-three candidates for the office, out of whom six were selected for a personal interview with the committee, and ultimately, as before stated, Dr. Niven was chosen. The appointment carries with it a salary of £850 per annum.

WE understand that Sir Joseph Lister, Bart., Prof. Pasteur, and Prof. Virchow have been the recipients of the distinguished order of S.S. Maurice and Lazarus bestowed by H.M. the King of Italy.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

DR. TUKE ON OVER-EXERTION OF THE BRAIN.—Dr. Tuke, in his first lecture delivered last week, announced that the subject of this series of Morrison Lectures on Insanity would be the *modus operandi* of over-exertion of the brain, especially during the earliest stages, as a cause of insanity. He first insisted on the misconception involved in speaking of insanity as a mental disease, a term which did not indicate the possibility of organic as contrasted with purely functional disease. If a case of acute mania or acute melancholia were presented at this date to the profession for the first time the symptoms would lead them to seek for some bodily disease accompanied by delirium, not a purely mental trouble. The cerebral convolutions were not sufficiently regarded as an apparatus in which changes may take place in consequence of the action of malign influences. It was difficult to comprehend mentally the structure of a convolution from ordinary descriptions in text-books, as the whole of the elements were not brought together in one place. With such a belief he had prepared a description of a typical Rolandic convolution following the statements of Ramon-y-Cajal and Retzius.

SEPTICÆMIA IN THE EDINBURGH MATERNITY HOSPITAL.—This hospital, we understand, is to be shortly closed, or even now has been closed, in consequence of an epidemic of septicæmia. Several consecutive cases occurred a little time ago, and since then no fresh patients have been admitted. The disease is either of the nature of puerperal septicæmia or due to some diptheritic poison introduced into the hospital.

ALLEGED CURES OF DRUNKENNESS BY TYSON'S SPECIFIC.—It is reported that all those who, as we before have drawn attention to, were put under this so-called cure for inebriety have completely recovered. During the "cure," they were allowed to go about their ordinary occupations, and no restrictions on their ability to procure alcohol were imposed. They report that now they have an unutterable loathing for alcohol in any form, and that they feel themselves able to withstand any of its temptations. We remember similar evidence in "the Keeley cure."

MEDICAL CHARITIES IN EDINBURGH.—Edinburgh has been described as a paradise for beggars. It may also be termed a paradise for the sick. If it is easy to make a fortune by begging in this city, it is no more difficult to get medical advice gratis. Emeritus Professor Struthers last week called attention to the fact that, while the total population of Edinburgh in 1889 was about 236,000, no fewer than 103,095 patients, indoor and outdoor, were treated gratuitously at the different hospitals and dispensaries. Of course this number included some country cases, but their number was not great enough to affect his argument. He especially decried the establishment of new and special dispensaries, whose work so often overlapped, while he thought that some central regulating board should be formed of competent gentlemen willing to look into the matter, in the hope that it might prevent such a waste of public money as was entailed by the present system. Dr. Russell, the Lord Provost of Edinburgh, re-echoed Professor Struthers' remarks, but thought that the matter was a most difficult one to settle, as too often the special hospitals and dispensaries had some private end, it might be of the attending medical officers to subtend, in whose interests the establishment was puffed far and wide. The time, however, has come when something should be done in Edinburgh in the way of regulating its medical charities.

THE REPRESENTATIVE COUNCILS—INTER-UNIVERSITY MEETING.—The Inter-University Conference of the Students' Representative Councils of Scotland was held on the 2nd inst., in the University Court Room. The Conference is an annual one, and is held in rotation at the four Universities of Scotland. It is now four years since the Conference was last held in Glasgow. Representatives were present from the Glasgow, Edinburgh, St. Andrew's, and Aberdeen Universities, each University having its full complement of four delegates. The delegates were photographed in a group before the Conference opened.

Glasgow Royal Infirmary.—The year's report of the Glasgow Royal Infirmary to hand is far from satisfactory, and shows a falling-off in the subscriptions, which has been going on steadily since 1886; in that year it amounted to £6,000, and has now reached the sum of £11,091 odd, and were it not for the Bellahouston bequest of £10,000, the deficiency this year would have been appalling. The falling off is said to be chiefly due to a decrease in the subscriptions from *employés* in public works. This, of course, should not be, but there is no denying the fact that the tendency is to allow these institutions to be kept up and managed by the moneyed classes, who derive no benefit, and who are too frequently and unjustly accused of fastening too tightly their purse-strings. At present 'tis the "working man" who has shown a callous indifference in withholding what gives him and his fellow-men a substantial return for his support.

The Churches and the Infirmaries.—A meeting was convened by the Lord-Provost in the City Chambers on the 31st ult., at which representatives of the three Infirmaries and the various religious denominations were present. An informal conference was held on the proposal that there should be one general collection on a fixed date in all the churches on behalf of the Royal Western and Victoria Infirmaries of Glasgow, and a committee was appointed to approach the churches with a view to carrying out the suggestion. The churches, it was pointed out, do not subscribe as they ought, and taking the Established Churches in Glasgow and Aberdeen as example, the former only subscribed £775, while the latter gave £1,038.

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (Feb. 5th), opened with a paper by Mr. Harrison Cripps on the treatment of a very difficult class of cases, viz., cases of suppurating ovarian cyst or pyosalpinx, in which a communication has formed between the cyst and the rectum. He read notes of four cases of the kind which had come under his notice among a hundred other ovariotomies. It is therefore—and fortunately—a rare complication. He tried puncture through the roof of the vagina in the first case in order to allow the opening in the rectum to close, but abdominal section became necessary. In the other three cases he resorted forthwith to this plan, with one death.

Mr. Goodsall suggested that it would be possible by inguinal colotomy to divert the passage of fæcal matter along the rectum and thus to facilitate the closure of the opening.

Dr. Cullingworth related four cases of his own in which he had operated on the lines laid down by Mr. Teale in his 1889 address. Mr. Teale's plan is to open the abdomen and endeavour to make out the nature of the abscess, then to open it and wash it out, stitching its edges to the parietal wound. This plan Dr. Cullingworth modified by removing the sac wall at the same time, with success. His last case was one in which a communication had been established with the bladder, but in this case too he followed his modified procedure with perfect success. He deprecated attacking these cysts from below, a plan which, he said, could never be expected to give satisfactory results.

Dr. Routh took up the cudgels on behalf of the practice of puncturing these cysts through the vagina or rectum. When an opening had been established naturally, he urged that it ought to be made use of to drain the cavity, and whenever the swelling was readily accessible from the vagina or rectum, he thought that the proper course was to withdraw the contents by means of the aspirator. If the pus was foul he washed out the cavity with a solution of iodine, and he claimed that having resorted to this method in several cases he had found it thoroughly trustworthy. He concluded by regretting the *furor secandi* which led present-day surgeons never to neglect an opportunity of opening the abdomen.

Dr. Garston read a paper dealing with the mutilations of the genital organs practiced by Australian aborigines on males and females for the prevention of procreation and otherwise. We hope to be enabled to publish this paper shortly.

GRESHAM UNIVERSITY FOR LONDON.

ROYAL COMMISSIONERS' REPORT.

The Royal Commission appointed to consider the draft charter for the proposed Gresham University for London have concluded their report, and the important document, having already been presented to Her Majesty the Queen, will, it is expected, be published shortly.

In respect to the constitution of the University, the Commissioners recommend that the Queen shall be the Visitor. The Chancellor, elected by Convocation, and holding office for life, to be the head of the University, and *ex-officio* a member of the Senate and of Convocation. He will preside over all meetings of the Senate. The Vice-Chancellor to be elected annually by the Senate from its own members, to be *ex-officio* a member of Convocation, of all boards and committees appointed by the Senate, and of the Academic Council. In the absence of the Chancellor he is to preside over all meetings of the Senate and be chairman *ex-officio* of all boards and committees appointed by the Senate and the Academic Council. The constitutional bodies of the University are to be the Senate, the Academic Council, the Faculties, the Boards of Studies, and Convocation. The Senate will consist of the Chancellor and sixty-five members appointed for four years, as follows: Three by the Crown; three by the President of the Council—one in respect of the Royal College of Science, one for the Education Department, and one for Art; one by the Secretary of State for the Colonies; one by the Secretary of State for India; nine by Convocation—two elected by the registered graduates in Arts, two by those in Science, two by those in Medicine, and one each by those in Law, Theology, and Music; two by the Royal College of Physicians; two by the Royal College of Surgeons; one by the Society of Apothecaries; four by the Inns of Court—one by each Inn; two each by the Incorporated Law Society, University College, King's College, and the London County Council, and one each by the Royal Agricultural Society, the Institution of Civil Engineers, the Royal Institute of British Architects, the Trustees of the British Museum, the Royal Society, the Governors of the City and Guilds of London Institute, the Corporation of London, and the Mercers' Company; four by the Academic Council, five by the Faculty of Science, four each by the Faculties of Arts and Medicine, two each by the Faculties of Law and Theology, and one by the Faculty of Music. Thus, of the members of the Senate, twenty-two will be elected by teachers, eight by the Crown, nine by Convocation, eleven by public bodies controlling medicine and law, four by public bodies connected with applied science, and eleven by various institutions. The Senate will be the supreme governing body of the University, and have authority from time to time to frame statutes—to be submitted to the Queen in Council and laid before Parliament—for altering or adding to the constitution, powers, or functions of the University. Further, it will be entitled to make, alter, or revoke ordinances for the regulation of all matters concerning the University, and to exercise all powers and do all things authorised to be exercised and done by the University. This will include the arrangement of the elections, the altering of the faculties, the admission and removal of schools, the appointment of professors, and the conferment of degrees. It is proposed that the Academic Council shall be composed of the Vice-Chancellor and fifteen members elected by the faculties to regulate teaching, examinations, and discipline. In certain cases it must consult with the Boards of Studies and with admitted institutions, but act on its own judgment. On various matters it will advise the Senate. The faculties will be made up of teachers, appointed or recognised by the University, in Arts, Science, Medicine, Law, Theology, and Music. They will send representatives to the Academic Council, elect the members of the Boards of Studies, and meet to discuss and report to the Academic Council. Their number and distribution may be altered from time to time by ordinance of the Senate. The constitution, functions, and mode of electing the Boards of Studies are duly set forth. Finally, Convocation is to consist of graduates, present and future.

We will refer to the new scheme in our next issue.

THE NORTH CAMP HOSPITAL AT ALDERSHOT.

We should like to know what is being done to carry into effect the recommendation of General Butler's Committee of Inquiry respecting the insanitary state of the North Camp Hospital at Aldershot. This hospital consists of a lot of old Crimean huts built 40 years ago and totally unfit, even then, for the accommodation of the sick according to modern ideas. The *Globe* of Dec. 23rd called attention to the fact that, notwithstanding the grant of money for the purpose of reconstructing the hospital, and notwithstanding the continuance of typhoid and other diseases of insanitation in that part of the camp, both soldiers and medical officers continue to be housed there. While these complaints have been made without result, plenty of money has been forthcoming for the building of churches, gymnasia, and engineers' barracks. The delay which has occurred, and is still occurring, in carrying into effect the advice of Gen. Butler's Committee is worthy of the attention of the Press and of Parliament, and we shall return to the subject as soon as further inquiries shall have been made.

We regret to announce the serious illness of Mr. Wheelhouse, of Leeds, Representative of the profession for England, and an ex-President of the British Medical Association.

An International Sanitary Conference is being held in Paris this week, to devise measures for the control of Cholera in the Persian Gulf, the Red Sea, and the Holy Places during the Mohammedan pilgrimage. Dr. Thorne Thorne and Surgeon-General Cunningham are the British representatives.

Dr Tibbitts was again unsuccessful in a libel suit brought on Monday last against *The Morning* newspaper. Even Mr. Harness's evidence on his behalf failed to secure for him a verdict.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE PROPOSED NEW ORDER OF MIDWIVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A request on the part of the Honorary Secretaries of the Midwives' Registration Association that I should become a member leads me to think that I have not made my position with regard to this question sufficiently clear in my letter to the Medical Press and Circular of Jan. 31st, 1894, on the subject of "Midwives and their Doings." I am altogether opposed to the formation of a new and distinct class of medical practitioner. This, I feel satisfied, must be the outcome of the proposed legislation. Nowhere have I seen any definite statement of the limitations to be placed on the practice of the registered midwives.

It is a comparatively easy matter to set the legislative ball rolling in the direction of education and registration; but it will be a very different matter when it is desired to put a limit to their privileges. With increased education we may rest assured that they will soon regard it as a grievance that they are not to be allowed to take complete charge of their cases, and of the children which they may bring into the world. The scheme is a distinct injury to the younger members of our profession, who will, by it, be deprived largely of their chances of practice, and of their opportunities of acquiring experience in midwifery. What I should like to see promoted would be the training of a good class of monthly nurse, who would know when to send for the medical man, and in the case of the child's being born before his arrival would be able to separate the child.

Before the members of the profession at large are asked to support a scheme for the further education of midwives, and their registration, I am satisfied that the first thing to be done is to define in the clearest possible terms how far they are to be permitted to take entire charge of their cases. It is only the fact that familiarity breeds contempt that leads people to regard lightly the process of parturition, and allows them to feel satisfied that it should be in the hands of other than properly qualified medical practitioners, as far as immediate supervision is concerned. Well-trained nurses might very properly have charge of confinement cases up to the time when the head begins to press on the perinæum, but from that time on, the case should be in the hands of the medical man. It is unnecessary for me to dwell upon the dangers of the parturient state. I would do all that lies in my power to prevent their being underrated. I am certainly opposed to the care of such cases being handed over entirely to the charge of midwives, however well trained they may be, unless their training has been carried to that point which would enable them to take complete charge in complicated as well as simple cases, *i.e.*, that they should be recognised as an entirely new class of practitioner. To enable them to do this a very much more extended course of instruction would be necessary than is, I think, contemplated by those who are moving in the matter of midwives' registration I trust that nothing will be done lightly in the matter. I hope that those who are advocating the registration scheme will state clearly the limitations they propose to place upon their midwives, and the machinery by which they propose to enforce their observance.

I am, &c.,

John W. Martin, M.D.,
Hon. Medical Officer to Jessop Hospital
for Women, Sheffield, &c., &c.

Claremont Place, Sheffield,
Feb. 3rd, 1894.

THE DERMATOLOGISTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The omission of Mr. Jonathan Hutchinson's name in the Presidential Address given by Mr. Malcolm Morris on "Dermatology of To-day" has, I think, been most justly brought before the profession in your number of January 31st. The address from "Open Sesame!" with the consequent unlocking of the doors of the secret caves of Pathology to the last sentence, where he states that in the hands of himself and a few others, "there need be no fear that the glorious heritage left us by our predecessors will suffer diminution, or that the traditional lustre of English dermatology will be dimmed," is really readable stuff, full of well-rounded periods and froth. It recalled the address he gave in Dublin on Ringworm, when with "ore rotundo" he told us what we all knew, but failed to give us the "tip" we all went for. Besides omitting the name of the most experienced, the most learned specialist, Mr. Jonathan Hutchinson, he made another omission when he dealt with treatment. Here he might have condescended to say a word or two regarding the well-recognised curative power certain mineral waters and baths possess in dealing with some of the most intractable forms of skin disease. Mr. Morris and every dermatologist knows that a course of mineral waters and baths often effects a complete cure when all the usual remedies, internal and external, have failed even to relieve; surely this system of treatment which has been had recourse to for centuries with the very best results should have found a place and taken precedence before such new fads as massage and electricity.

As I am writing, I may as well state that, having had

Dr. Byrom Bramwell's treatment of psoriasis with thyroid extract brought very forcibly before my notice when at the British Medical Association Meeting at Newcastle, in August last, although I did not believe in the miraculous cures recorded, I determined, having many suitable cases under treatment at the time, to give it a fair, full trial. I did so, in psoriasis, lichen, prurigo, eczema, syphilitic psora and rupia, and after steady exhibition of the best preparations I never found the slightest sign of improvement which I could credit this new-fangled remedy with.

I am, Sir, yours, &c.,
A. S. Myrtle, M.D.

Harrogate, Feb. 1st, 1894.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is apathy on the large field of workers in dermatology at the present time that certain individual names forming the basis of a "dermatological club" should be held up to light as they were recently at an address given at one of the London medical societies, when names were excluded who long before the present age of dermatologists were known to fame, such as the elder Startin who established the first skin hospital and whose lectures were published in the *Medical Times and Gazette*; Mr. Jonathan Hutchinson, whose writings and works are so well known; Purdon, of Belfast; Smith, of Birmingham, and other good workers in London were omitted in this favoured list. It had been better and certainly more courteous if names had been omitted, with the exception of those "gone before," than have thus so pointedly individualised. It seems a suitable time when a Dermatological Society might be formed on the same basis as the medical societies of London, open to all members of the profession.

I am, Sir, yours, &c.,
A Dermatologist of 18 Years' Standing.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Will you allow me to express my great regret at the tone in which you have recently, in two articles, criticised the Dermatological Society of London. Your wish is, I believe, to assist those, of whom I am one, who desire to see a new society formed on a wider basis. Our aim and hope is that the two societies will work side by side in a friendly manner for the advancement of the knowledge of dermatology. This aim will not, however, be accomplished without some forbearance on both sides, for, as is not unnatural, there are some of the members of the old society who regard with suspicion the formation of a new one. Now I feel sure that your criticisms are calculated not to diminish, but to increase the state of tension which already exists, and apart from that, they are, I am sure, wholly undeserved. The old society has done excellent work, and has been conducted throughout on liberal and judicious lines. It merits your applause, and not your blame.

The new society will be in a sense supplementary to the old one and in no way its rival, for their scope of work will be very different. The old society is a purely clinical and almost private one. We meet together for the inspection of examples of rare disease, which we discuss in conversation. We make no speeches, we admit no reporters, we publish nothing. Our meetings are, however, for mutual instruction invaluable. Most of us are already teachers, and the knowledge we there obtain is quickly transmitted to our classes and thus becomes indirectly a public possession. That our number is restricted to thirty ought not to become a taunt, for it is obvious that such a society could not work with a crowd. I sincerely hope that we shall long flourish on our old lines, and that it may long be as it is now, a coveted honour in the dermatological world to be one of the thirty.

Some of us believe that, so far from there being any antagonism, the formation of a new society, on broader lines, is really the only means likely to secure perpetuity to the older one without prejudicial modifications. The new one will enlist as its members all suitable applicants, and thus save the older from injurious pressure from without. It will receive, it is hoped, many of our younger men and of those who, though by no means professed dermatologists, yet take interest in the study of skin diseases and syphilis as important departments of general medicine and surgery. As vacancies may occur in the ranks of the thirty, it will hope to supply worthy candidates who have been trained in its ranks, and the senior society has passed almost unanimously a resolution advising its members to join the new one.

I am, Sir, yours, &c.,
Jonathan Hutchinson.

◆

HOMŒOPATHIC CLAIMS TO DISCOVERIES OF MEDICINES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—For one who boasts that he has made a "quasi-experimental study" of homœopathy, it is strange that Dr. Granville has so completely misunderstood the system as shown by his observations in your periodical of this week.

No one ever denied that homœopathy has taken from the traditional materia medica hundreds of remedies, but the merit of Hahnemann consists in his discovery that those medicines, and the others which have been introduced into homœopathic practice by Hahnemann and his disciples, cure diseases by virtue of their power to cause in the healthy human body morbid states or symptoms similar to those of the diseases they can cure. Perhaps Dr. Granville will be surprised to learn that Hahnemann in his very first essay enunciating his therapeutic rule gives a list of 53 drugs from the annals of the old school which are said to have cured diseases whose symptoms strongly resembled those recorded, in these same annals, as having been caused by poisonous or excessive doses of these same drugs. In the first four editions of the *Organon* he gives 25 more instances of the homœopathic use of drugs from allopathic authors. Among these 78 remedies enumerated by Hahnemann as showing the unconscious employment of drugs homœopathically in the old school will be found most of the homœopathically inducted remedies in Dr. Brunton's book. But Hahnemann's method of testing medicines on the healthy human body in order to ascertain their powers enabled him to add a vast number of other powerful substances to his materia medica many of which were completely unknown to old-school practitioners, or if ever used had been discarded because the old school did not know how to employ them usefully. It is not because Dr. Brunton employs the same medicines as homœopathy does, but because he directs them to be used in accordance with the homœopathic therapeutic rule, that we assert that he has borrowed these medicines and their indications from homœopathy.

Dr. Granville's assertion that "all substances which have any action on the organism produce two apparently opposite and contradictory effects, resulting from their exhibition in different doses" is quite erroneous. Hahnemann recognised the frequent occurrence of a primary and a secondary action of drugs which were often the opposite of one another, but that was no way dependent on difference of dose, for one single dose would suffice to display this effect.

The imaginary therapeutic virtues ascribed to the drugs in the old work quoted by Dr. Granville have no bearing whatever on their homœopathic uses.

I am glad to observe that Dr. Granville denounces "that crime against common sense which is unhappily approved by the majority of our so-called 'leaders,' namely, the treatment of homœopaths as outside the pale of professional sympathy." The sentiment is excellent; the pity is that he does not act up to it, for expressions like "infatuated believers in infinitesimal doses," "the whole pretence is a juggle," "preposterous claims to originality," can hardly be considered as striking examples of "professional sympathy."

Homœopathic writers are always ready and willing to acknowledge the sources whence they derive their medicines; they have no need or wish to appropriate to themselves the discoveries and inventions of others to which they have no legitimate claim, as is sometimes done by members of Dr. Granville's school, as, no doubt, he is well aware.

I am, Sir, yours, &c.,
R. E. Dudgeon.

53 Montagu Square.
February 1st.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Whilst acknowledging the general fairness of Dr. Mortimer Granville's tone in the article on "Homœopathic Claims" which appeared in your last issue, and whilst granting him the same right to freedom of opinion that he is willing to allow to others, I must ask your leave to point out that, in spite of his ernest endeavours, he has failed to comprehend what homœopathy is, and what are the claims of its followers. I accept Dr. Granville's assurance that he learned from Nicolas Lembert and from Hahnemann the use of camphor in influenza; but when Dr. Granville seeks to shield Dr. Brunton with the same ancient authority, and when he makes out that homœopathists claim for Hahnemann the discovery of all the drugs he experimented with, as distinguished from their special and precise uses, I must demur. Taking Dr. Granville's list and comparing Lembert's descriptions of the drugs,with the pictures of the same in Hahnemann's *Materia Medica*, anyone can see that the provings on healthy individuals have brought out characteristic features and indications of curative properties that were never dreamed of by former writers. Lembert seems to have found each remedy more or less "detersive," and the general terms of his descriptions were the very thing that disgusted Hahnemann with old physic and made him seek for something better. That Dr. Brunton did not compile his "Index of Diseases and Remedies" from Lembert is plain to the meanest understanding. In this "Index," appended to his *Pharmacology and Therapeutics*, 1st edition, will be found among the remedies advised under "Tonsillitis" a medicine named *apis*. Now *apis* is a preparation of bee-poison, of which there is no mention at all in the body of Dr. Brunton's work, the reference given telling only of "honey" and "wax." It will hardly be contended that Dr. Brunton found his indication for this valuable homœopathic remedy in Lembert.

Like most writers who fail to understand homœopathy, Dr. Granville is quite prepared to "explain" it. His explanation is not new, indeed, some homœopathists have adopted it. For my own part, I do not accept it; but it does not matter, for homœopathy is not based on explanations, but on facts. It is not a fact that all drugs produce opposite effects in large and small doses; some may do *some*times, in *some* individuals, but the only "opposite" of most symptoms is health. More often there is an alternating action, or a series of differing effects. In homœopathy a remedy can be used when indicated by any of these effects, provided the other symptoms of the remedy correspond to the case under treatment Opium in considerable doses produces constipation, and it also, in the same doses, produces diarrhœa, and it has cured both when given in doses much too small to cause either. Again, opium produces sleeplessness as well as drowsiness, in fact, some persons cannot be made to sleep by opium, even in large doses. Correspondingly, homœopathists may use it to cure both conditions when induced by some other cause. But it must always be remembered that in homœopathy the whole of the symptoms and all ascertainable abnormalities of each patient must be considered; prescribing on one symptom alone is sure to lead to failure. It is purely gratuitous on Dr. Granville's part to say that homœopathy cannot be allowed the credit of curing unless the drug is given to the sick in as large a dose as has produced the condition in a healthy person. Hahnemann began the practice of homœopathy in that way, but he soon found it necessary to diminish his doses, not because he did not make cures, but because the large doses caused such violent aggravation of the sufferings before the cure took place. Dr. Granville talks about "infinitesimal doses" as if the word "infinitesimal" had any definite scientific meaning. Where does "small" end, and "infinitesimal" begin? Is a decimilligramme of Koch's lymph an infinitesimal dose?

I am, Sir, yours, &c.,
John H. Clarke.

◆

"MEDICAL MISSIONARIES!"

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue of Jan 31st, Dr. C. H. F. Routh attempts to reply to my remarks made on the above subject. He draws copiously from "Walker's Dictionary" when defining the words "medical" and "diploma." I am not now concerned in dictionary definitions, I prefer to take the Medical Act, 1886, as my guide. That Act provides that any person who wishes to be qualified to practise either medicine, or surgery, or midwifery, must now study for five years, and pass a qualifying examination in these three subjects. This is the law on the matter. Dr. Routh, in his zeal for the nigger and other folks, says, hang the Medical Acts! we shall start an examining body of our own, and grant them diplomas. Is such conduct honest? My opinion is, that such conduct is "infamous in a professional respect," and that Dr. Routh should be brought before the General Medical Council. If any other person breaks a law in this country he is liable to be punished. Why, therefore, should these diploma-granting concerns escape, even when sailing under the "religious" flag and backed up by *such* patrons. Dr. Routh refers to other persons who are selling or granting diplomas. Do two blacks make a white? Does it matter whether these "religious" missionaries are trained for one, two and a half, or three years? Has not the Medical Council—a body composed of men from all the medical examining bodies in the United Kingdom—made a rule to the effect that each student must have a *minimum* educational period of two years? In actual practice Dr. Routh says this is nonsense, when niggers and other destitute people are being treated. Why does he not apply the same reasoning to the poor and destitute in England, and say that a medical training of one or two years is sufficient for those who treat our own poor? I am asked, Is it true that medical men can *never* treat *women* in India? No, it is not true. It is open for *every* women in India to go to any practitioner, man or woman, privately, or in hospital, and obtain treatment. If they are stupid enough not to do so that is their fault. Dr Routh proposes to meet their sweet obstinacy by driving a coach and four through our Medical Act. But, if they *will* object, send them perfectly qualified medical women, and not illiterate persons. Again, Dr. Routh refers to the fact that "shoals of women kill their female children" in China. Agreed. Do they not do the same here? Are there not thousands of women in England who to-day (Sunday) go to church, and after copulation syringe themselves out, or if pregnant, take a few doses of a mixture guaranteed to remove "all obstructions"? Yet, are we to repeal the Medical Act—in its educational sections—because child-murder is frequent?

Next, he refers me to the feet of poor girls placed in hard shoes. I reckon one need not go to China or to India to see such contemptible nonsense, and I question if the custom would be affected by swarming the country with even "medical" missionaries.

Dr. Routh gives a copy of the Diploma issued by the "Zenana Medical College," and in that diploma the owner is stated to be entitled to treat persons suffering from diseases and to practise surgery and midwifery; in fact, act as we medical practitioners now do. Is this honest and fair? Are the Missionary Societies now so poor, or is their case so weak that they cannot obtain the funds necessary to send out properly-educated practitioners Because, this diploma-granting business is one of the heaviest blows which have been given to true missionary enterprise. I note that Dr. W. M. Ord is stated to be the Examiner in Medicine at the "Zenana Medical College." I thought he had refused to act any further in this respect. Do Mr. T. Pickering Pick and Dr. W. R. Dakin still act as Examiners in Surgery and Midwifery?

Yours, &c.,
Robert R. Rentoul.

Liverpool,
February 5th.

DENTAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Mr. Blandy deserves the thanks of the whole profession—medical and dental—for the plucky fight he is making against the grosser forms of quackery, but it is a hopeless fight. It is out of the question to expect that any Act of Parliament will in our time be introduced to prohibit the practice of any department of medicine or surgery for gain by the unqualified. It is possible more stringent laws might be passed against illegal assumption of titles, but it would be difficult to devise a law which would prevent the use of designations quite sufficient to deceive the public and lead them to look upon a quack as a qualified man.

As to advertising I recommend to Mr. Blandy a study of the columns of the *Times* during the last few weeks ending with this. He will there see a lengthy correspondence on the "Puffing System" in which it is clearly proved that the journalistic trade depends upon this system. The vast majority of newspapers either depend for a living or depend for their profits on paid puffs. With the exception of the *Times* and a few leading papers the whole newspaper press, and especially those ostensibly devoted to exposure of quackery, humbug, and financial fraud, are, in fact, subsidised and supported by the army of sharp and roguish traders and quacks of all denominations. Mr. Blandy has the general press against him; their living or their worldly gains depend on the continued flourishing existence of the classes against whom he fights, and so the fight is, I repeat, hopeless.

I am, Sir, yours, &c.,

X. Y. Z.

London, Feb. 1st, 1894.

PROFESSIONAL, ESPECIALLY DENTAL, ADVERTISING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I wish I could encourage Mr. Blandy and those who are joined with him in the effort to put a stop to advertising by dentists, in the hope that they will succeed in getting the Medical Council to declare advertising to be "infamous conduct in a professional respect." Not even if the whole dental profession were inspired by the enthusiasm of Mr. Blandy would the Medical Council be induced to do this, because the Council well knows that, if it fulminated any such restrictive ordinance, it would have to face a screech by the Radical party in Parliament which would give it infinite trouble and bring it into much odium with the liberty-of-the-subject people. Those who aim at the suppression of professional advertising will do much better if they will devote their energies to the task of inducing the English and Scotch Colleges to obtain charter powers, if they do not already possess them, to deal with such cases, as the Irish College of Surgeons has for many years done. The Colleges are very much their own masters, and, if they have such powers, can, if they have the back-bone, exercise their authority (as the Irish College did in Partridge's and many other cases) without any hesitation and without the apprehension that their action would be reviewed by Parliament.

The qualified dental surgeons undoubtedly suffer much more than any other section of our profession from these advertising traders, but they must excuse me for saying that it serves them right. When the Dentists Act was promoted by Sir J. Tomes and Sir J. Lubbock in 1878 the dentists (even the very party who now groan under the incubus of low-class practice and advertising dentistry) insisted in co-opting into their profession every hairdresser, tobacconist, barber, or chemist's tooth-puller who chose to give himself a diploma into their profession. Every effort which the *Medical Press and Circular* could make, week after week for months, was made to arouse the dentists to the danger thus incurred, but in vain. Like the nurses and the plumbers and all the others who think registration is another name for Heaven, the dentists would have it at any price, and at a stroke of Sir J. Tomes's pen they took to their bosom about 4,600 such people, the majority of whom did not even pretend that they had had any dental education or, in fact, were dentists at all. The dentists proper now find themselves overwhelmed by their co-opted competitors and driven out of competition by men who have no hesitation in resorting to methods which no self-respecting professional man would adopt, and I greatly fear that they can do nothing but endure the discomforts of the matrimonial bond into which, with their eyes open and in spite of every warning, they deliberately entered, and wait for the demise of their hopelessly irreclaimable partner.

As to the proposal to agitate for a change of law in the direction of absolute suppression of unqualified medical or dental practice, I say with regret that, in my opinion, no combination of parties in our profession could carry such a proposition in this age of free trade and Radicalism, though I fully believe that, if the public could be got to form a calm judgment on the matter they would see the advantage to the community of such a change of law.

I am, Sir, yours, &c.,

An Old Hand.

Obituary.

DR. EWING WHITTLE, OF LIVERPOOL.

We regret to announce the death of this highly esteemed member of the profession, which took place on the 28th ult. Deceased was born in Liverpool in 1814, and was the son of Mr. James Whittle, of Liverpool, and afterwards of Westport, Ireland, where Dr. Whittle's early years were passed. After a distinguished career in the Dublin Schools of Medicine, he proceeded to the University of London, where he obtained with honours the degree of M.B., and was awarded a gold medal, subsequently graduating M.D. He settled in practice in Liverpool, where he remained until he retired in 1886. He was a former president of the old School of Medicine, and on the institution of University College, became its first lecturer on Forensic Medicine. In medical jurisprudence he was regarded as an expert, and he was frequently consulted in matters of medico-legal inquiry. He was elected a member of the Royal Irish Academy, and for many years was a well-known member of the Literary and Philosophical Society of Liverpool, in which city he took a keen and active interest in public affairs, especially in matters of social and moral reform. In former years Dr Whittle was a contributor to this and other leading medical journals, but of late little has emanated from his pen. He has an only son, Dr. Glynn Whittle, who is in practice in Liverpool, and is Physician to the Lying-in Hospital in that city.

◆

Literature.

ST. THOMAS'S HOSPITAL REPORTS (a).

The present volume opens with a sympathetic obituary of Mr. F. Le Gros Clarke, from the pen of Mr. Wagstaffe, and it is illustrated by a beautiful photogravure portrait of the subject of the notice.

We cannot do more than call attention to some of the eighteen communications the present volume contains, together with the usual surgical and medical reports. We regret to find that the surgical report is still without any statement on the anæsthetics used, and the results obtained, facts which could not fail to interest the profession.

The following important announcement prefaces the surgical report:—

"Koch's treatment has been tried in several cases of tuberculous, joint, and skin affections, producing a general reaction in all, and a local reaction in skin cases, but apparently no local change in joint cases. No benefit was derived from the treatment in any case."

That the use of iodoform and carbolic acid has been discontinued we were prepared for. Some years hence the antiseptic paraphernalia of to-day's surgery will be the ridicule and scorn of our successors.

The contributions to the volume are fully equal to any of former reports, and all are instructive and interesting.

Dr. Stanley Kent writes on the function and structure of the mammalian heart, a paper deeply interesting to those who know Pettigrew's classical monograph on the subject, and one of great practical bearing on the treatment of cardiac troubles.

Mr. Truman's paper on two cases of epulis which come away entire, attached to the teeth will well repay reading, and we believe will much affect surgical practice in such cases.

(a) "St. Thomas's Hospital Reports." Edited by Dr. T. D. Acland and Mr. B. Pitts. Vol. xxi. London: J. and A. Churchill. 1893.

Diphtheritic paralysis is the subject of Dr. Mackenzie's paper, which is a continuation of his communication to the last number of the Reports on Albuminuria after Diphtheria. We hope that Dr. Mackenzie will publish a reprint of both papers. They are full of such useful information as the physician needs almost daily, and which on this subject we have not seen so well or dearly given elsewhere.

The exigencies of space prevent our giving notice of the other papers of the volume, one and all of which will repay study.

◆

DERMATOLOGY. (a)

FOR the general practitioner, no better selection could have been made by the New Sydenham Society than the present volume of "Selected Monographs on Dermatology."

No class of diseases are more troublesome to treat than those of the skin; so much depends in them on heredity, occupation, and nourishment; and so many of them simulate other diseases of the same class, that to deal with them successfully the prescriber must study the subject; and he cannot in that study have a better guide than "Selected Monographs on Dermatology."

To have the best works of Unna, Nielsen, Duhring, Bronson, Blanc, Berger, and Prince-Morrow, is to be rich in the therapeusis of skin diseases.

"Drug Eruptions" by Prince-Morrow, is worth more than a year's subscription of the Society, and is of the most practical character. He enumerates close on one hundred drugs which have produced rashes, and gives a reference to the published cases. At the end of the monograph there is a general bibliography and a good index.

We select this monograph to give some idea of the usefulness of the volume, and to make known to our readers something of the great work the New Sydenham Society is doing.

It is enriching English medical literature with the choicest and best writings of Continental and American authors; it is placing in the hands of its members the most advanced and approved methods of therapeusis, and none of its members, who avails himself of the advantages, need dread falling behind in the scientific pursuit of medicine.

TRANSACTIONS OF THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL SOCIETY. (b)

THE present volume of Transactions opens with an excellent address on the "Compatability of Conservative and Aggressive Surgery," by the President, Dr. McFadden Gaston, of Atlanta, Georgia, whose name and writings are familiar to many of our readers. The writer very ably shows that aggressive surgery is truly conservative, the aim and end of surgery being the preservation of life, the conservation of function, and the remedying of deformity. Thirty-seven papers follow, all of which deal with subjects of practical interest, and they are made more valuable by the publication of the discussions which they called forth.

In his paper, "Craniotomy not Justifiable," Dr. Kellock mentions the interesting fact that in regions of Central Africa "some women have been known to do it (the Cæsarian operation) on themselves," and that "the African laparotomist washes his hands and instruments, and bathes the abdomen of the patient with palm wine, such as was used by embalmers in ancient times," a very curious fact when we consider the aseptic properties of alcohol, and that in olden times Saxon leeches bathed wounds with red wine.

Dr. Baxter's paper on the radical cure of inguinal hernia is a clear and brief description of a very promising operation, the various steps of which are illustrated by exquisite photogravures.

As might be expected in the home of McDowell and Marion Sims, ovariotomy receives a great deal of attention and Dr McMurtry's paper, "Some Complications of Ovariotomy," gave rise to a very interesting discussion. Surgical treatment of the brain in epilepsy was dealt with by Dr. Hadra.

Thoughout, the Proceedings testify eloquently to the industry, research, and originality of the Southern surgeon. The work of this great society gives promise that in the future, as in the past, the work of the Southern surgeon and physician will lead the way in scientific medicine.

◆

YEO'S THERAPEUTICS. (a)

THE study of disease from the point of view of treatment is always interesting. The work of the physician is, when all is said and done, the treatment of disease: preventive and curative.

Although the older writers usually considered diseases from the clinical point of view the method gradually was displaced; still a few writers such as Fothergill, Brunton, and Beale, successfully reverted to the old plan and produced very readable and instructive books, and Dr. Yeo has been equally successful. His two volumes of "Clinical Therapeutics" extending almost over the whole range of practical medicine are replete with valuable teaching, and the information is clearly and plainly given from the author's own experience supplemented by some selected prescriptions of other physicians.

The work does not profess to be exhaustive, neither does the author go out of his way to disprove the theories of other writers with whom he does not agree; but having arrived at a definite conclusion he clearly puts forward his views and the treatment he bases on them.

Some of the subjects might, we think, have had more space devoted to them, to dismiss specific infective diseases in 130 pages is, doing scant justice to the subject. Varicella is dismissed in seven lines, and in the seven lines there is nothing told by which the disease may be recognised or distinguished from a mild attack of small-pox. Rötheln has five lines given to its description and treatment; now it is just such minor ailments that puzzle the beginner. He does not meet them in hospital, and the majority of writers, like our author, do little more than name them. The unfortunate beginner fails to recognise chicken-pox or German measles which are promptly diagnosed by some matron friend for the young mother and the poor medical practitioner is dismissed.

A clinical handbook should not be deficient on these subjects—every book treats fully of typhoid and typhus, and many medical text-books deal fully with obscure nervous diseases which the beginner can hardly be expected to recognise, but the public expect, and justly expect him to be familiar with minor ailments and minor surgery.

We dwell on this fault in an otherwise valuable book because we think it should be corrected in the next edition. A few more pages will add nothing to the expense of the book, and they will remove the only flaw it has.

As a book for the practitioner, hospital resident, and senior student, we strongly recommend it as clear, intelligible, practical, and thoroughly reliable.

◆

WEISSMANN'S GERM-PLASM. (b)

WORKERS on the boundary line of the known trying not only to advance into the trackless territory beyond, but to make a path for followers labour under the difficulties that beset all pioneers, they are too often hampered by the errors of their predecessors.

In scientific research a theory is almost indispensable to progress, yet the theory is misleading unless it is based on ascertained facts, and such facts are hard to get in the initial stages of progress.

Readers of the "germ-plasm" theory will find the work to be far from light literature, withal interesting. To fully grasp the author's premises that "the germ-plasm is composed of vital units, each of equal value, but differing in character, containing all the primary constituents of an individual," and familiarise the mind with the evidences in favour of the theory requires the undivided attention of the reader.

(a) "Selected Monographs on Dermatology." Unna, Neilsen, Duhring, Blonson, Blanc, Berger, Prince-Morrow. London: The New Sydenham Society. 1893.

(b) "Transactions of the Southern Surgical and Gynæcological Society. Vol. v. Fifth Session. Held at Louisville, Kentucky.

(a) "A Manual of Medical Treatment or Clinical Therapeutics." By I. Burney Yeo, M.D., F.R.C.P., Professor of Clinical Therapeutics in King's College, London. London: Cassell and Company, Limited. 1893.

(b) "The Germ-Plasm: A Theory of Heredity." By August Weissmann, Professor in the University of Freiburg. Translated by W. Newton Parker, Ph.D., Professor in the University College of South Wales, and Harriet Römfeldt, B.Sc. London: Walter Scott, Limited. 1892.

The author lays down almost as an axiom the statement that :—" The germ-cell of a species must contain as many determinants as the organism has cells or groups of cells which are independently variable from the germ outwards."

On the question of repair of tissue he writes :—" The simplest cases of regeneration are due to the freely-formed tissue, consisting of similar cells, always containing a reserve of young cells, which are capable of replacing a normal or abnormal loss."

The question is too big to be dealt with in the columns of a weekly ; we can do no more than give an outline of the author's views, selecting such points as bears on medicine. Ably as the views are put forward, we cannot affirm that the reasoning is conclusive, or that the facts might not in some instances bear other interpretation. Throughout, however, the book is deeply interesting, and is one of the most important contributions to the subject ever made, ranking with *hangenesis* theory of Darwin and Herbert Spencer's correlated theory of " units."

Withal its fascination for the biologist and the medical pathologist the book cannot be described otherwise than as dry.

◆

POZZI'S GYNÆCOLOGY. (a)

This, the third volume, completes Professor Pozzi's splendid work on gynæcology. In our notices of the two former volumes we freely expressed our admiration of the book, and on reading the present volume, we find that the same care and trouble has been expended as in the preceding volumes.

Whilst such monographs are produced by the New Sydenham Society, there are many and strong inducements to those members of the medical profession who are not members to join. They will consult their own interests by doing so.

◆

Medical News.

French Hospital and Dispensary.

The Twenty-Sixth Annual Dinner in aid of this Institution took place at the Whitehall Rooms on Saturday last (Feb. 3rd), His Excellency, M. Decrais, the new French Ambassador, in the chair. The Lord Mayor was prevented assisting by an attack of bronchitis. Many members of the *corps diplomatique* were present. The annual report testified to the ever-increasing usefulness of this cosmopolitan charity, receiving as it does French-speaking foreigners irrespective of nationality. Special mention was made of the services rendered by the indefatigable Secretary, M. Fernand Sorel, and the usual toasts were enthusiastically responded to, the intervals between them being agreeably filled by a varied musical selection.

Royal College of Surgeons of England.

The following are the lecture arrangements for the current Session :—

Dr. E. H. Starling commenced a Course of Three Lectures on "The Physiology of Lymph Formation" on Monday last, and will continue it to-day, and on Friday next.

Professor C. B. Plowright will then deliver three Lectures on "The Fungus Kingdom," commencing on Monday, Feb. 12th.

Professor E. Treacher Collins will follow with Three Lectures on "The Anatomy and Pathology of the Eye," commencing on Monday, Feb. 19th.

And Professor Charles Stewart will deliver Nine Lectures on "The Physiological Series of Comparative Anatomy in the Museum of the College," commencing on Monday, Feb. 26th.

The Course of Lectures will be concluded in May and June by Mr. J. H. Targett and Professors Raymond Johnson, William Thorburn, and T. Pickering Pick.

All the Lectures will be delivered on Mondays, Wednesdays, and Fridays at 5 o'clock p.m. precisely each day.

Fellows and Members of the College are invited to attend.

Gentlemen who are not Fellows or Members of the College will be admitted on presentation of their private visiting card at the door of the Theatre.

The Health of Dublin.

So much has been said of the appalling mortality within the City of Dublin, and of the expediency of great and costly works to sanitate the city, that it is worth while for us to quote the figures supplied by the Registrar-General for the quarter ending the 30th of December. It appears from them that the Dublin death-rate for the quarter, so far from being so terrible as has been represented, has been actually 0·2 per 1,000 less than that for the similar quarter of the previous ten years. The rate stood at 27·30, as against 23·2 and 23·2 in Glasgow, Edinburgh, and London. The zymotic rate showed a great improvement on that of the previous quarter, but was 0·7 per 1,000 over the average. Typhoid caused 91 deaths, being 30 over average, and influenza was also very fatal, having caused 30 deaths, against 19 for the preceding three months.

Arsenic for Horses.

Some of our readers may recollect the case of the poisoning of several of the stud of Captain Steeds, of Clonsilla, near Dublin, a few years since. It was then ascertained beyond a doubt that they had swallowed handfuls of arsenic, and the only question which remained for elucidation was how, when, and by whom it was administered. A prosecution which took place at Spalding, in Lincolnshire, recently may throw some light on the subject. A local chemist was arraigned for having sold a pound of solid arsenic to the groom of a local farmer, who administered a quantity of it to three horses, upon the advice of a fellow-servant, with the result that three of them died. The chemist was fined £5 in each case and costs for having sold the poison.

Bequests to Dublin Hospitals.

By the will of Mr. Gervas Taylor, of Molesworth Street, Dublin, we understand that most of the Dublin Hospitals and many Church of Ireland Charities will benefit to a considerable extent. He is stated to have left £80,000, of which charities will receive £40,000, the Stewart Institution amongst others receiving £25,000. We have reason, also, to believe that Mr. Taylor marked his appreciation of the skill and long-continued care of Mr. Ormsby of the Meath Hospital by leaving him £3,000. Mr. Taylor's wealth was derived from the trade in tobacco of the old firm of Hunt and Taylor, of which he was the surviving partner.

Army Medical Service.

The following is a list of Surgeons on probation of the Medical Staff of the British Army who were successful at both the recent London and Netley Examinations, arranged according to merit :—

	Combined Marks.		Combined Marks.
Prynne, H. V.	4,736	Cameron, K. M.	3,980
Master, A. E.	4,635	Fleury, C. M.	3,717
Dansey Browning, G. ..	4,327	Fox, A. E.	3,657
Clarke, E. S.	4,078	Green, S. F.	3,628
Barnett, K. B.	4,051	Tibbits, W.	3,456
Boyle, M.	4,015		

Indian Medical Service.

List of surgeons on probation in Her Majesty's Indian Medical Service who were successful at both the recent London and Netley Examinations, arranged in order of merit.

	Combined Marks.		Combined Marks.
a Lamb, G.	5,634	Pennett, H.	4,385
b Burden, H.	5,188	Harriss, A.	4,318
Leumann, B. H.	4,602	Berry, A. E., ...	4,304
Fisher, J.	4,578	Macleod, E. C.	4,282
Peck, E. S.	4,479	Thomson, C.	4,045
Evans, C. H.	4,419	Fraser, H.	4,032

a Gained the Herbert Prize of £20 with the Martin Memorial Gold Medal, the Parkes Memorial Bronze Medal, the Montefiore Second Prize, and a Prize in Pathology presented by Professor A. E. Wright, M.D.

b Gained the Montefiore Medal and Prize of 20 guineas, and the Prize in Clinical Medicine presented by Surgeon-General W. C. Maclean, C.B.

(a) "A Treatise on Gynæcology, Clinical and Operative." By S. Pozzi, M.D., Professor in the Faculty of Medicine, Paris. Vol. iii London : The New Sydenham Society. 1893.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

F.R.C.S.—If our correspondent will forward the case we shall be pleased to accord space to it.

HEAR BOTH SIDES.—Your letter received appears to be outside the question of "disinfection," and raises points about which our readers are not concerned. The matter, however, will be considered.

DR. HUXLEY (Maidstone).—We hope to have space for your communication in our next.

A COUNTRY PRACTITIONER.—We have instituted inquiries in every likely quarter, and failed to gain any information as to the existence of such an invention. The suggestion we made in a former number of a light behind glass seems the only feasible solution.

THE LOCAL GOVERNMENT INVESTIGATION AT CARRICKMACROSS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I trust you will kindly allow me to correct a mistake which appears in your comments on the late Local Government Board inquiry held in Carrickmacross. The "bitterest enemy" referred to was not the Chairman of the Committee, but a Guardian for the division, who is also a member of the Committee. The Chairman, Thos. Mee, Esq., is one of the most fair-minded gentlemen I have ever met, and could not possibly lend himself to the contemptible proceedings referred to.

I am, Sir, yours, &c.,
W. J. KISBY, Med. Officer.

Dispensary House, Corduff.
Feb. 3rd.

MR. E. WILLIAMS.—We can give you no further information than that vouchsafed in our last. The Secretary would probably afford you the required details

Meetings of Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 7TH.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m. Specimens will be shown by Dr. Probyn-Williams, Dr. Boxall and others Dr. Robert P. Harris (Philadelphia): A Plea for the Practice of Symphysiotomy, based upon its Record for the past Eight Years (communicated by Dr. Lewers). Annual Meeting: Election of Officers and Council. The President's (Dr. Herman) Annual Address.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton, at 4 p.m., Dr. C. Y. Biss: Cases of special interest. Royal London Ophthalmic Hospital, Moorfields, at 8 p.m., Mr. A. Q. Silcock: Glaucoma.—Hospital for Skin Diseases, Blackfriars, at 1 p.m., Dr. Payne: Impetigo and Contagious Suppuration.

ROYAL COLLEGE OF SURGEONS.—At 5 p.m., Dr. E. H. Starling: The Physiology of Lymph Formation.

WEST LONDON HOSPITAL (Hammersmith).—At 5 p.m., Dr. Ball: Demonstration of Throat Cases. (Post-Graduate Course).

THURSDAY, FEBRUARY 8TH.

BRITISH GYNÆCOLOGICAL SOCIETY.—At 8.30 p.m. Specimens:—Dr. Heywood Smith: Uterus and Appendages completely Removed for Fibroma.—Mr. Jessett: (1) Uterus Removed per Vaginam for Malignant Disease; (2) Uterus Removed per vaginam for Multiple Fibroma. President's Address.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Gt. Northern Central Hospital, Holloway Rd., N.).—At 8.30 p.m. Cases and Specimens will be shown by Drs. Day, Wight, and Walker, and Messrs. Lockwood, Kendall, and others.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond Street, at 3.30 p.m., The Surgical Registrar: Pathological Demonstration of Surgical Specimens.—National Hospital for Paralysed, Bloomsbury, at 2 p.m., Dr. Charlton Bastian: Selected Cases.—Central London Sick Asylum, Cleveland Street, W. at 5.30 p.m., Sir William McCormac: Cases in the Wards.

FRIDAY, FEBRUARY 9TH.

CLINICAL SOCIETY OF LONDON.—Adjourned Discussion on Mr. John D. Malcolm's case of Nephrectomy for Malignant Tumour in a Patient under Two Years of age. Mr. Arbuthnot Lane: (1) Multiple Epitheliomatous Growths developing in Psoriasis treated with Arsenic more than Thirty Years. (2) Acute General Suppurative Peritonitis Secondary to Appendicitis, Removal of Appendix, Recovery.—Dr. Lauder Brunton and Mr. Watson Cheyne: A case of Intestinal Obstruction due to Constriction of the Bowel after Appendicitis.—Mr. John B. Lunn: Fungating Growth of the Penis lasting Nineteen Months.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton, at 4 p.m., Dr. C. Y. Biss: Cases of special interest.

ROYAL COLLEGE OF SURGEONS.—At 5 p.m., Dr. E. H. Starling: The Physiology of Lymph Formation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—At 8 p.m., President's Address: Recent Developments in State Medicine.—Dr. T. Donnelly: The Sanitary Administration of Dublin.—Dr. McDowel Cosgrave: Liquor Habit Curers.—Dr. H. C. Tweedy: Some Points in Connection with the Administration of Hospital Relief.—Dr. Ninian Falkiner: Public Practice: an Experience.

SATURDAY, FEBRUARY 10TH.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital, at 11 a.m., Dr. Hyslop: Developmental Insanity, Circular Insanity.

MONDAY, FEBRUARY 12TH.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Dermatitis Exfoliata and Pityriasis Rubra Pilaris.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. Plowright: The Fungus Kingdom.

Vacancies.

Coombe Lying-in Hospital, Dublin.—Assistant Master. Applications to the Master. (See advert.).

Guildford and Godalming Joint Hospital Board.—Medical Officer. Salary £175 per annum. Applications and testimonials to the Clerk to the Joint Board on or before Feb. 19th.

Leeds.—Hospital for Women and Children.—House Surgeon. Salary £75 per annum. Applications to the Secretary.

Owens College, Manchester.—Professorship of Zoology. Applications to the Registrar on or before April 3rd.

Ramsgate and St. Lawrence Royal Dispensary and Seaman's Infirmary.—Medical Officer (unmarried). Salary £120 per annum, with furnished apartments, gas, firing, and attendance. Applications and testimonials to the Sec. on or before Feb. 6th.

Royal Surrey County Hospital, Guildford.—Resident House Surgeon. Salary £80 per annum, with board, lodging, and laundry. Applications and testimonials to the Hon. Sec. on or before March 10th.

Salford Royal Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications and testimonials to the Institution on or before Feb. 15th.

St. Leonard, Shoreditch.—Medical Officer of Health. Salary £[illegible]00 per annum. Application forms to be obtained from the Clerk at the Town Hall before Feb. 13th.

Appointments

BUTLER, G. H., L.R.C.P. Irel., L.R.C.S., L.M. Edin., Medical Officer to the Wealdstone Sanitary District of the Hendon Union.

GORDON, J. F., M.D. Irel., Medical Officer to the Branch Workhouse at Mayhull, Parish of Liverpool.

HICKIE, Dr., Medical Officer to the New Ross Union.

LYLE, T., M.D., C.M. Glasg., Medical Officer to the Throat and Ear Hospital, Newcastle-on-Tyne.

MCGEE, W., L.K.Q.C.P., L.R.C.S. Irel., Public Vaccinator for the Shire of Poowong and Jeetho, Victoria, Australia.

MEADE-KING, R. L., M.B., B.S. Durh., M.R.C.S., L.R.C.P., Assistant House Surgeon to the Devon Hospital.

MODLIN, J. G., M.B., B.S. Dunelm, Honorary Surgeon to the Monkwearmouth and Southwick Hospital, Sunderland.

MOLONEY, P., M.B. Melb., Honorary Physician to St. Vincent's Hospital, Melbourne, Victoria, Australia.

NICHOLSON, A., M.D. Lond., L.R.C.P., M.R.C.S., Honorary Surgeon to the Sussex Eye Hospital, Brighton.

OLDHAM, C. J., L.R.C.P. Lond., F.R.C.S., Honorary Surgeon to the Sussex Eye Hospital Brighton.

RYAN, J., Medical Officer to the Clonashe Dispensary.

SHAW, R. H., B.A., M.B., B.Ch. Univ. Dub., House Surgeon to Mercer's Hospital, Dublin.

TILDESLEY, J. P., L.R.C.P. Lond., M.R.C.S., Medical Officer to the Willenhall Sanitary District of the Wolverhampton Union.

Births.

ATKINSON.—Jan. 29th, at Camberwell New Road, S.E., the wife of W. A. Atkinson, M.B., of a son.

BAMPTON.—Jan. 29th, at Brookfield, Ilkley-in-Wharfedale, the wife of Augustus H. Bampton, M.D., of a son.

Marriages.

BONAR—NIELSON.—Jan. 31st, at Glasgow, Thomas Bonar, M.D. Edin., to Elizabeth Christian (Elsie), daughter of William Neilson, Esq., of the Bank of Scotland.

COLLINS—HERRICK.—Jan. 31st, at Holy Trinity Church, Brompton, Edward Treacher Collins, F.R.C.S., of 47 Devonshire Street, W., second son of the late Dr. W. J. Collins, of Regent's Park, to Hetty Emily, eldest daughter of the late Lieutenant-Colonel J. L. Herrick, of Ouga Ouga, Hawke's Bay, New Zealand.

RANDALL—ANSELL.—Feb. 1st, at St. Mary's, Wimbledon, Philip N. Randall M.B., Surgeon R.N., to Ethel, eldest daughter of William J. Ansell, F.R.C.S., of Wimbledon.

Deaths.

BARRETT.—Jan. 23rd, at Heywood, Lancs., William Barrett, M.R.C.S., L.R.C.P., aged 80.

CARDEW.—Jan. 25th, at Dennington Park, West Hampstead, Harry Warnell Denton Cardew. M.R.C.S. Eng., aged 33.

HOPKINS.—Jan. 24th, at Berkeley Place, Wimbledon, Nathaniel Hopkins, Surgeon-Major, Bombay Army (retired), aged 60.

KNIGHT.—Jan 26th, at his residence, Freshfield, Liverpool, Samuel Ratcliffe Knight, B.A., M.B., Ch.B., aged 40.

LEPPINGTON.—Jan. 21st, at Great Grimsby, Hildyard Marshall Leppington, M.R.C.S.E., J.P., aged 85.

MCCLEAN.—Feb. 1st, at the residence of his son-in-law, Dr. A. H. Jacob, 23 Ely Place, Dublin; Francis McClean, Esq., Surgeon-Dentist, formerly of 10 Stephen's Green, aged 88.

MURRAY.—Jan. 25th, at his residence, Elm College, Forres, John Murray, M.D. Aberd.

SAUNDERS.—Jan. 24th, at Tenterden, Kent, Edwin Dawes Saunders, M.R.C.S., in his 88th year.

STEDMAN.—Jan. 2[illegible]th, at Flushing, Arthur Stedman, M.R.C.S., of Gt. Bookham, Surrey, aged 69.

ON

PERITONITIS. (*a*)

By FREDERICK TREVES, F.R.C.S.,

Surgeon to and Lecturer on Surgery at the London Hospital; Examiner in Surgery University of Cambridge.

LECTURE II—(*Abstract*).

THE CAUSES OF PERITONITIS.

EVERY addition to our knowledge of inflammation of the great serous membrane tends to make the classification of its various forms more and more simple. It has now become evident that peritonitis depends almost entirely, if not entirely, upon infective processes, and that these agencies are concerned, directly or indirectly, in every form of the disease.

There are those who maintain that there is no form of peritonitis which is not due to infection, and although the data upon which such an assertion is based are not entirely perfect, there is yet much presumptive evidence in favour of its accuracy. Indeed, the domain of non-infective peritonitis is becoming rapidly more and more dubious.

In dealing with any classification in which an infective process is the main element there are many general considerations to be borne in mind. On the one hand there is the dose of the poison, and on the other hand there is the soil into which it is introduced. The dose must obviously be liable to considerable variations, not only in amount but also in virulence, while the conditions offered for growth by the inoculated body must differ to even a wider and more complex extent.

The resistance of the individual to the growth of septic organisms is influenced by a multitude of circumstances, the value of which is scarcely susceptible of being formulated. There are questions of age and of health, and of such unfavourable affections as Bright's disease, diabetes and alcoholism. There are local conditions which lend themselves to the more ready cultivation of germs, such as extensive damage to the peritoneum, and extensive interference with its functions of absorption—or, at least, with that ill-understood power it possesses of dealing with noxious micro-organisms. There are the presence of ascites and the co-existence of extravasations of blood, bile or intestinal matter in the peritoneal cavity. There is, finally, the entirely undefined peculiarity of the individual which appears to alone render one man susceptible and another almost exempt.

In the great majority of instances peritonitis depends upon what Tavel and Lanz (*b*) call "continuity infection." By this is understood the direct spreading of the infection to the peritoneum from a neighbouring tissue other than the serous membrane. Under such heading would be included peritonitis following hernia or any visceral lesion or disease capable of producing the trouble, puerperal peritonitis, most forms of pelvic peritonitis, and certain varieties of tuberculous peritonitis. It would exclude the larger number of the cases of inflammation of the serous membrane which follow accidental or operation wounds.

The following classification of peritonitis according to its cause appears to be justified by our present knowledge of the subject.

(1) *Peritonitis due to infection from the intestine.*—Under this heading are included most cases of peritonitis associated with hernia, with intestinal obstruction, and with perforation; peritonitis due to any form of ulceration of the bowel; to enteritis; to cancerous growths of the gut and to troubles in the appendix. There will also be included peritonitis due to inflammatory changes in the biliary canals, and some forms of peritonitis following upon operation.

The micro-organism which is usually found associated with these different forms of peritonitis is the bacterium coli commune.

(2) *Peritonitis due to infection from without.*—This division will include puerperal peritonitis, peritonitis consequent upon inflammatory troubles in the genital organs or in the parietes of the abdomen, and some forms of peritonitis following upon operation.

The micro-organisms usually associated with the varieties considered under this heading are pyogenic cocci and notably the streptococcus pyogenes.

(3) *Peritonitis due to the pneumococcus.*

(4) *Tuberculous peritonitis.*

(5) *Peritonitis of a doubtful nature.*—Under this purposely indefinite heading it will be convenient to discuss—(*a*) Peritonitis due to irritants; (*b*) forms of the trouble reputed to depend upon rheumatism, gonorrhœa, syphilis, Bright's disease and alcoholism; and (*c*) peritonitis met with in the newly born.

(1) PERITONITIS DUE TO INFECTION FROM THE INTESTINE.

As already stated, the micro-organism which appears to be usually answerable for the numerous forms of peritonitis met with under this heading is the bacterium coli commune. This most remarkable and common bacillus was first described by Escherich (*a*) in 1885. Its definite pathogenic properties remained imperfectly recognised until 1889, when they were expounded by Laruelle (*b*), by Roux and Rodet, (*c*) and many others. Within the last few years the literature appropriated to this little organism has become so extensive as to be almost overwhelming (*d*).

The morphology of the bacillus—with which we have no concern in this place—has been elaborately dealt with by Wurtz, (*e*) Macaigne, and other writers.

It has been shown to be identical with the bacillus pyogenes fœtidus obtained by Passet in 1885 from the stinking pus of a peri-rectal abscess.

The bacterium coli commune exists normally in the human body, and is found in individuals in a state of perfect health. It has been demonstrated to be pre-

(*d*) One of the most valuable monographs is "Le Bact. Coli Commune, son Rôle dans la Pathologie," by Dr. Macaigne. Paris, 1892. Another good general account is by Malvoz (*Arch. de Med. Exper.*, 1891, p. 593), and another by Welch (Trans. "Congress of American Phys. and Surg.," vol 2.

(*e*) *Archiv. de Med. Exper. et d'Anatom. Pathol.*, Jan. 1, 1893.

sent along the whole length of the alimentary canal from the mouth to the anus. (*a*) Its natural habitat is the bowel. It is said to be especially numerous in the duodenum (*b*) and in the colon, and has been found in the bile passages.

It is certainly the most abundant and the most constant of the bacteria found normally in the human body, and has been estimated to form 95 per cent. of the micro-organisms met with in the bowel of man. Sternberg (*c*) gives a list of forty-eight micro-organisms which had been isolated from human fæces or the contents of the intestine. Of this number twenty-five are non-pathogenic, and of the pathogenic forms not a few represent the same bacillus under different names. There is no doubt that special names have been given to micro-organisms which are mere variations of one common form.

The bacterium coli commune has a striking feature in that it appears to vary in virulence.

So far as experiments upon animals are of value it would seem to be quite harmless when taken from the normal intestine. A culture of the bacillus so obtained has no effect when injected into the peritoneum of animals. (*d*)

If, however, the bowel become the seat of certain diseased conditions (or it may almost be said of *any* diseased condition), then the bacillus becomes at once virulent.

Virulence has been found to be developed in cases in which the bowel was obstructed, strangulated or inflamed, in venous congestion of the gut, in œdema of the bowel wall, in diarrhœa, in typhoid fever and in cholera.

In a case of diarrhœa produced by tartar emetic, this colon bacillus was found to have become virulent. (*e*).

It also appears to develop qualities for evil in instances of advanced constipation. In any case experiments show that the virulence when once developed may vary considerably in degree.

When the intestine is healthy, the bacterium coli commune has little disposition to escape through the gut wall or to invade the tissues of the body after death. If, however, the intestine be damaged or diseased, then the bacterium shows an active inclination to penetrate through the bowel wall, and is usually found to have extensively invaded the tissues after death. (*f*) The disposition of the bacillus to pass through the intestinal wall under the circumstances just stated is well illustrated in examples of slight degrees of strangulation of the bowel produced by experiment in animals. (*g*)

It has been clearly demonstrated that the bacterium coli commune can produce pus after inoculation. It has been found in man in a state of almost pure culture in the pus from an ischio-rectal abscess. So far as the human subject is concerned, it has been shown that these various forms of peritonitis which are assumed to be of intestinal origin depend mainly and in many instances solely upon the bacterium coli commune.

In peritonitis associated with hernia, the colon bacillus is the micro-organism most commonly found in the sac. This is the case in all stages of strangulation, and is independent of the character of the fluid, the bacilli being obtained in cases in which the fluid in the sac is copious and opaque, as well as in those in which it is clear and scanty.

The colon bacillus has been shown by Cornil, Babes, and others to be almost exclusively the bacterium concerned in perforative peritonitis.

Barbacci (*a*) states also that it is practically the only bacillus to be produced in cultures from the exudation in perforative peritonitis in man. The same applies to perforative peritonitis produced experimentally in dogs. In this form of peritoneal inflammation, the other micro-organisms found in fæces develop in the serous cavity, but only for a time. The bacterium coli commune alone survives. Barbacci points out that the liberal development of this bacillus is greatly favoured by the presence of such a medium as is provided by the fluid contents of the intestine, a material which readily damages the peritoneal endothelium. He considers that death is due to absorption partly of the bacterial products, and partly of the noxious chemical matters contained in the intestinal fluid which escapes into the belly cavity. In the same way it has been demonstrated that this micro-organism is the active agent in the majority of cases of peritonitis starting from the appendix.

This bacillus has also been found in cases of peritonitis following operation, and on this subject Dr. Welch writes as follows (*b*) :—"Its presence several times in pure culture, in laparotomy wounds treated aseptically, although apparently not a source of serious trouble, was not a matter of indifference. It was generally accompanied with moderate fever, and a thin, brownish, slightly purulent discharge, of somewhat offensive but not putrefactive odour. The smooth and rapid healing of the wound was interfered with. In some of the cases there was evidence of intestinal disorder."

In the cases of peritonitis after laparotomy in which the colon bacillus is found, it is probable that such an injury had been inflicted upon the intestinal peritoneum at the operation as to permit the bacterium to escape through the bowel wall. It has been shown that it requires but little damage to the bowel or to its serous covering to allow of such escape.

It is well known that pneumonia is not an uncommon sequel of peritonitis, and it is possible that in certain of these cases the colon bacillus is the active agent. It has been found in the pleura when pleurisy was present (Laruelle), and has been obtained by puncture from the hepatised lung some days before death from peritonitis (Macaigne). Fisher and Levy give two cases of strangulated hernia with pulmonary complications, and in both instances the colon bacillus was found in the affected parts of the lung. (*c*)

Finally, it has been assumed that some of the constitutional symptoms attending severe constipation may be due to the absorption of the products of this widely diffused bacillus.

The exudation associated with the bacterium coli commune when it attacks the peritoneum is often characteristic. It is well seen in cases of inflammation about the appendix. The fluid is at first clear and greenish-looking. It then becomes greenish yellow, thin, semi-opaque, and foul-smelling. If it pass on to suppuration, the pus has no especial characters except that it is frequently offensive. In chronic cases there is sometimes produced a white, soft, custard-like material which is often met with in operations upon the appendix during the quiescent period, and which I do not think is changed pus nor a residuum left by pus. In some long-standing cases I have scraped away a full teaspoonful of this matter from about the cæcum.

In concluding the account of this variety of peritonitis it may be pointed out that the irritant which induces the peritonitis, and which reaches it from the intestine may follow more than one path. (*c*) Bacteria

may escape through a perforation in the bowel; (*b*) they may pass through the wall of a segment of intestine which has been in some degree damaged, but not perforated; and (*c*) chemical products of bacteria may reach the peritoneum by either one of these routes.

(2) Peritonitis due to Infection from without.

It has been already observed that this variety of peritonitis usually depends upon pyogenic cocci. Of these the streptococcus is the one most usually met with. It is often alone, or it may be found in association with other micro-organisms, among which, however, it is the chief. That the streptococcus is the usual agent in puerperal peritonitis has been shown by Widal, Bumm, Fränkel, and Courtois-Suffit. (*a*) It has been met with in association with putrefactive bacteria in examples of perforative peritonitis by Predœhl and others. The staphylococcus is very rarely met with alone in cases of peritonitis, and is usually associated with the more virulent forms of coccus. So far as experiments go it has been shown that injections of pyogenic cocci into the peritoneum act more vigorously if mixed with a fluid difficult of absorption, or if introduced with a corrosive fluid capable of damaging the peritoneal endothelium.

The pyogenic cocci, and most usually the streptococci, have been met with in cases of peritonitis after operation in man, and experiments upon animals show how the noxious effect of those micro-organisms may be assisted by extravasations in the peritoneal cavity, by long exposure of the peritoneum, and by damage to its delicate surface. In the operation cases it is most probable that the streptococcus gains an entrance through the wound. In puerperal peritonitis it, no doubt, reaches the abdomen through the pelvic organs following the veins or lymphatics, or the Fallopian tube.

In the rare examples of peritonitis associated with erysipelas of distant parts (such as the face) the streptococcus must be assumed to reach the serous membrane through the blood. (*b*)

(3) Peritonitis due to the Pneumococcus.

This variety of peritonitis has not yet been so soundly demonstrated as to possess an indisputable existence. In the first place, the connection of the pneumococcus with pneumonia is a subject about which there is much conflicting evidence. In the second place, peritonitis is a very rare sequela to pneumonia, although it is true that pneumonia is not an uncommon complication of peritonitis.

The pneumococcus has been found in the peritoneum in a large number of the subjects of fatal pneumonia, and yet the serous membrane has remained sound. In 151 autopsies in which the pneumococcus was demonstrated, Netter (*c*) found only two cases of peritonitis.

However, cases of peritonitis have been reported by Weichselbaum (*d*), Courtois-Suffit (*e*), Sevestre (*f*) Nelaton (*g*), and Galliard (*h*), in which the pneumococcus appears without doubt to have been the cause of the inflammation.

The peritonitis in some of these cases was primary, and was the sole disease, in the other instances it was secondary to ordinary pneumonia. The pneumococcus would seem to be at one time noxious to the peritoneum, and at other times to be harmless. It is difficult to localise it in the peritoneum of animals by experiment.

(4) Tuberculous Peritonitis.

This variety of peritonitis will be dealt with in Lecture IV.

(5) Peritonitis of a Doubtful Nature.

(*a*) Peritonitis due to irritants. On the subject of this form of peritonitis there is much conflict in opinion. If its existence be established, then the existence of a non-infective variety of peritonitis has to be at once acknowledged.

Bumm (*a*) maintains that a non-infective peritonitis may be produced by mechanical, chemical, or thermal irritants, and states that it is usually plastic and localised.

Pawlowsky injected sterilised croton oil into the abdomens of twelve animals. Of this number eight died from hæmorrhagic peritonitis, and neither pus nor micro-organisms were found in the exudation, nor were there any signs of sepsis.

As a comment upon these experiments, it may be noted that pyogenic cocci (*e.g.*, the staphylococcus aureus) will act more readily, and in smaller doses if introduced into the peritoneum together with some corrosive fluid capable of injuring the serous endothelium, and further that such injury to the peritoneal surface—in cases in which no cocci are injected—encourages the escape of the colon bacillus from the intestine.

Fränkel injected Tr. iodi and Liq. ferri perchlor. into the peritoneum of certain animals. Peritonitis followed. If the exudation were examined at an early stage, or in the slightest cases, it was found to be clear and free from micro-organisms. If, however, the case were advanced, the exudation was purulent and swarming with bacteria which had passed through the bowel wall.

A like explanation would appear to be adapted to an experiment by Thompson (*b*), who found that a piece of wadding dipped in 1 in 1,000 solution of corrosive sublimate and placed within the abdomen caused in some animals a fatal peritonitis.

Jalaguier (*c*) showed that tampons of sterilised gauze introduced into the peritoneal cavity of dogs caused no symptoms and no reaction, and when the animals were killed at the end of some months the gauze was found rolled up in a ball and encapsuled by adhesions. It was made evident, moreover, that it needed a foreign body of a certain size to even excite adhesions.

Fæces, if introduced into the peritoneal cavity, cause peritonitis, not by chemical action, nor as an irritant, but by reason of the micro-organisms or their products contained in the extravasation. (*d*) If the material be sterilised no effect follows. Fresh filtered fluid from the bowel caused, when injected into the abdomen, a fatal peritonitis in the exudation of which the bacterium coli commune was found. The same fluid when filtered through many layers of gauze produced abdominal symptoms, but all the animals lived. When the fluid was sterilised it had no effect.

The same results have attended the injection of human bile into an animal's peritoneum. When the bile was untreated peritonitis usually followed, but when it was sterilised the injection was attended by no evil results.

According to Naunyn, (*e*) normal bile is sterile. According to Létienne, (*f*) it may contain bacteria. It is said by others to be sterile so long as it contains free biliary acid.

In inflammatory conditions of the bile passages the bacterium coli commune is commonly found.

Lähr (*g*) has shown that in man a considerable

effusion of bile may take place into the peritoneal cavity without causing peritonitis.

Blood is not of itself capable of producing peritonitis, although it affords a very favourable condition for the development of any bacteria which may gain access to the extravasation.

This fact may be considered to be proved by the experiments of Penzoldt (*a*), Cornil and Ranvier (*b*), and others, and by the operation of peritoneal transfusion of blood performed on man by Ponfick (*c*), Golgi and Raggi (*d*).

Orth (*e*) believes that it is possible to set up peritonitis by injecting a large quantity of blood into the cavity. He considers that it induces inflammation not so much through the action of bacteria as through the development of some fibrin ferment. Mr. Herbert Page (*f*) has published three very interesting cases of peritonitis from hæmorrhage, but it is evident from the reports that the peritonitis was of very slight degree and of very secondary importance.

A consideration of the whole matter leads to the conclusion that the production of peritonitis by non-infective irritants has not yet been satisfactorily proved.

◆

HOMŒOPATHIC CLAIMS

TO

DISCOVERIES OF MEDICINES.

By MORTIMER GRANVILLE.

II.

I have no desire to be drawn into a discussion of the so-called *principle* of homœopathy, but as I have, confessedly, laid myself open to the attack of Drs. Dudgeon and Clarke, particularly the last mentioned, it is only courteous to them and just to myself to reply. They differ on some points but agree in the inference from my short paper that I know nothing of their "system." Dr. Dudgeon deems it strange that I have "so completely misunderstood" it, and Dr. Clarke observes that "like most writers who fail to understand homœopathy" I am "quite prepared to 'explain' it;" and then, no doubt with a view to demonstrate the hopeless imbecility of the explanation I offer, he proceeds to point out that it "it is not new, indeed some homœopathists have adopted it." He even, while remarking that "it is purely gratuitous on Dr. Granville's part to say that homœopathy cannot be allowed the credit of curing unless the drug is given to the sick in as large a dose as has produced the condition in a healthy person," goes so far as to admit that "Hahnemann began the practice of homœopathy in that way." So that after all it cannot be "so strange" as Dr. Dudgeon seems to think it that I have "so completely misunderstood the system ' considering that the discoverer of that system, himself at first formulated the therapeutic rule as I have interpreted it.

These critical gentlemen must please to understand that my acquaintance with homœopathy commenced just fifty years ago, when I was myself very successfully treated for a severe attack of pleuro-pneumonia by the late Dr. Chepmell, having been some two years previously far less agreeably conducted through a similar illness with the aid of three full bleedings from the arm, four free leechings, and blisterings of the amplest description under the beneficent care of Drs. Tweedie and Roots, and Mr. Dalton. Certainly, Dr. Chepmell's method with "small" though not by any means "infinitesimal"—*pace* Dr. Clarke – dose of aconite and belladonna (or was it bryonia?) proved infinitely preferable. My last experiences of homœopathy were acquired in 1850 and 1851, when I am bound to say some of my results were so satisfactory to patients who had no notion *how* they were being treated, that I was hunted up years afterwards with urgent requests to prescribe "the same medicine." May I confess that the last straw which broke the camel's back of my endurance was a large trunkful of books on homœopathy kindly lent me by my very old and much respected friend the late Dr. Cronin. This contribution included the two-volume materia medica of Jahr and Grüner, and such then recent works, as the Treatises of Curie—an excellent name for a doctor—Laurie, Headlam, and others, whose names have escaped me. I read them all, and studied the Materia Medica, making copious notes of "provings" and "indications" as I went, even to the "absence of religious opinions" credited to the virtues, or vices, of colocynth. The eclipse of my faith was consummated when Mr. Trotman, another of Hahnemann's own pupils, supplied me with statistics showing the success of homœopathic treatment as compared with that of the Vienna "expectant" system, which consisted in giving no medicine at all. As Mr. Trotman very frankly pointed out homœopathy could only boast of one-quarter per cent. advantage in respect to a single malady; and we both agreed that this *might* have been purely accidental. Such was the general impression on my mind that I acted on the suggestion, and arrived at the conclusion to which I still, on principle, adhere, that the smallest possible interference with the workings of natural law in sickness as well as in health, is the best and most successful "system" of life preservation, and the safest method of fighting the duel with death.

If Hahnemann had lived a little longer, I believe he would have arrived at the conclusion that his first impressions of the fact he lighted up were right, and that, as Curie use to explain it, "the remedies employed carried the organism quickly and safely over" the wave that threatened to swamp it, or "by a slight change in the direction of the force"—as for instance, by the bat of the skilful cricketer—deflected the deadly missile so that it fell harmlessly; or, which amounted to the same thing, so modified the course of the tempest-borne bark that it escaped the rock, or protected the wicket by an inclined plane that gently turned the ball aimed at it wide a-field.

Drs. Dudgeon and Clarke are, of course, perfectly cognisant of the fact that *similia similibus curantur* has no necessary, nor even legitimate, connection with "the system of infinitesimal doses." The first is homœopathy, the second is—may I write it?—*humbug*.

When Dr. Clarke talks of "a decimilligramme of Koch's lymph" and asks if this is "not an infinitesimal dose," he either indulges in a pleasantry, or he is *strangely* forgetful of the fact that a single germ of living matter has within it all the potentiality of illimitable multiplication. For aught we know, a single tubercle bacillus may have the power of killing a full-grown man by tubercular phthisis. No one in his right senses can pretend that an infinitesimal dose of "hepar sulphuris," of "carbo-vegetabilis," or of any other of the substances with which the whole atmosphere we inspire is loaded, can possess any potency comparable to the minutest conceivable molecular of Koch's lymph. As well compare the tread of a fly's foot with the crushing blow of a Nasmyth's hammer. The recollection of Dr. Dudgeon will readily carry him back to the date of which I first spoke, about 1844, when Dr. Chepmell treated me as I have described, and he will probably be able to correct my assertion if wrong, that the tincture of aconite used by homœopaths of that day was a dilution of exceedingly pure and active tincture in the progressive proportion of 9 to 1, so that one drop of No. 1, would be equivalent to the 1-10th of a drop of our tincture of aconite, with this difference that pharmaceutists, working on the lines of the British

Pharmacopœia, can never produce anything comparable with the tincture prepared, as it used to be prepared, by the homœopaths. This is, I believe, the true explanation of the earlier successes of homœopaths on which they have thriven ever since. There is much of great practical value in the researches of Hahnemann and his pupils, and the introduction of the system itself did good. Let who will deny it, the impression homœopathy produced in London at least, on the more intelligent classes of the community, so reacted upon the practitioners of the healing art generally, that they no longer resorted to such formidable measures of depletion, or so heavily drenched their patients with nauseous drugs as was the practice in the old days when so distinguished and respected a physician as Lettsom found chalked on the wall of his lecture room—

I bleeds 'em, and I sweats 'em,
And if they die, I lets 'em.

I confess that to me the practice of to-day which consists mainly in neutralising acids, and stupefying nerve centres, with "soda or potass," and bromides and chlorals, respectively, is not one whit more respectable in a scientific sense, but it is at least more merciful and perhaps—though I doubt it—a little less destructive, than the wholesale life-squandering of the "antiphlogistic" method. If some new "system" as plausible and fascinating as homœopathy, and equally innocent of directly injurious consequences were to "take the town" again, possibly a new impetus might be given to practical medicine by which the sick would be as much the gainers as they unquestionably were by the growth and popularity of the fallacies of Hahnemann.

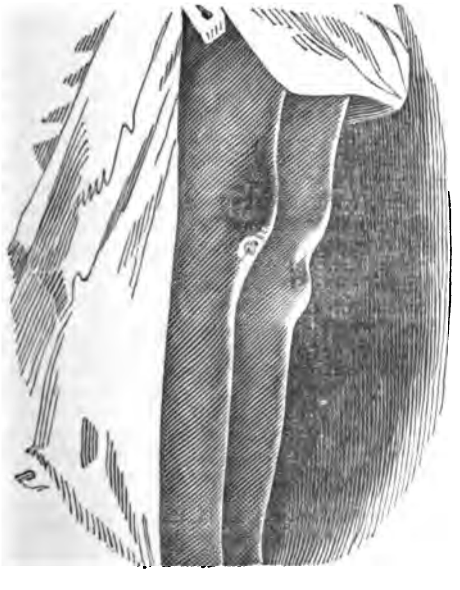
SPONTANEOUS FRACTURE OF BOTH PATELLÆ.

By DAVID BALDWIN JACOB, M.D., F.R.C.S.I.,
Surgeon to the Queen's County Infirmary.

P. M., æt. 32, states that four years previous to admission he suffered dislocation at the left patella, which was reduced and treated by a bone-setter, the dislocation recurred shortly after, with like treatment and a few weeks following the last he, in consequence of supposed slight muscular effort, spontaneously fractured the same patella transversely; he consulted the bone-setter, who told him he could give him no aid; he states that he had not professional advice, but desired to go to hospital from which he was dissuaded, with the result of the permanent infirmity shown in the illustration.



Three months ago a slip provoked muscular effort enough to cause transverse fracture of the right patella four days previous to his admission to the Queen's County Infirmary, when he was found to have considerable effusion into the synovial membrane, and about two and a half inches separation of the fragments and some tenderness. The illustration is taken from a photograph produced three months after the accident. Apparently there is close and complete osseous union with excellent relative position, but an only appreciable lateral displacement of the fragments by each other. The knee-joint continues somewhat stiff, but improves under treatment, and apparently there is every prospect of a very useful limb, especially needed in consequence of the permanent injury to the other.

The treatment adopted was the application, above and below the patella, of strips of rubber adhesive plaster, the fractured surfaces having been brought into proper position by an assistant. These straps were chiefly for protection under the following arrangement, a posterior splint having been attached in the ordinary way, a pair of wooden cylinders of 3/8 inch section (large cedar pencils) were placed transversely one above one below the patella, and were fixed backwards at the proper pressure by unyielding ties to the splint; the cylinders were then caused to approximate each other by sufficient and regulated tension of elastic rubber bands placed between them at each side. Lastly, anteriorly, the fragments were fixed in the same plane by a padded disc of firm poroplastic felt secured by a bandage.

As already stated the union appears to be osseous and complete, and there is accordingly no reason to regret that the contemplated wire suturing was abandoned. A slight superficial slough resulted from perhaps undue pressure by one of the cylinders, but proved of no importance.

The treatment was little painful and possessed the advantage of minimising obstruction of circulation. It is even doubtful that rendering the means of support concave, to fit the outline of the patella, would carry advantage, as comfort would perhaps be purchased at the expense of blood supply.

THE EARLY LITERATURE OF INFLUENZA.

By HY. REYNOLDS PEYTON, L.R.C.P., L.R.C.S., L.M., &c.,
Medical Officer of Scotstown District, Monaghan.

The following extracts from an interesting paper of Dr. Thompson's which was read before the London Medical Society on February, 15, 1839, are I think extremely interesting at the present time.

To Dr. Thompson's observations may be attached more or less deep interest from the fact that during the reading of this paper before the Sociey it transpired he had made himself conversant with the peculiarities of influenza by various references to authors of repute reaching as far back as the 14th century, giving dates and authority for his observations.

He gave a minute description of the symptoms characteristic of the complaint referred to, and also laid stress on the most prominent, such as—

Pyrexia, slight or great.
Catarrh of a mild or aggravated type.
Pains in the head.
Lassitude, &c.

Dr. Thompson goes on to say: "The disease was first mentioned by Hippocrates, but became frequently prevalent in England at the beginning of the 14th century.

"Since then it has continued to occur at various periods in this and other countries, the attacks varying in intensity and the characteristics of the disease differing."

The author mentioned the chief peculiarities of the disease during former centuries and also in the beginning of the present century, and then deduced from the historical detail the following :—

That we are visited by this affection every ten years.

Of all epidemics it was the most destructive.

That it left a modification of atmosphere for years after it raged, which induced those affections which usually accompanied influenza such as bronchitis, pneumonia, catarrh.

The disease when unaccompanied by any other affection was of itself seldom fatal.

When organic disease did exist it was productive of very fatal consequences.

Complications depended on that portion of the body which was weakest, in one being the head, in another the lungs.

It took a course from the west towards the south and then north.

The average period of duration was six weeks.

It had been ascertained that in certain places where the epidemic had raged the atmosphere had become so modified as to affect visitors who arrived a long time after the disappearance of the disease.

Regarding the cause of influenza, this varied as much as the symptoms.

He (Dr. Thompson) should place the affection very low in the scale of contagiousness, regarding its origin as due to presence of noxious matter floating in the atmosphere.

It had been noted by some authorities that thunderstorms of a more or less severe nature preceded the outbreaks.

As regards the treatment opium, which had been used formerly, was found injurious. Recourse was usually had to castor oil and mercury.

Selected Prescriptions and Therapeutic Notes.

54.—For Impetigo :—

℞ Adipis,
Vaseline, āā, ʒiij ;
Acid salicylatis, gr. vij ;
Zinci oxidi, ʒiss ;
Plumbi diacetatis, gr. v.
M. Dr. Dubreuille.

55.—The following is also useful in Impetigo :—

℞ Vaseline, ℥iiss ;
Acid boracis, ʒss ;
Zinci oxidi, ʒss ;
Acid salicylatis, gr. vij.
M.

56.—An Antiseptic Powder :—

℞ Iodoformi, ℥xxxj ;
Pulv. benzoini, ℥xxxj ;
Quinquiniæ, ℥xxxij ;
Magnes. carb., ℥xxxj ;
Ol. eucalypti, ℥iv.
M. Lucas Championniere.

57.—Sulphur Lotion for Acne :—

℞ Sulphuris sublim., ℥iss ;
Sp. camph., ℥iv ;
Aq. destill., ad, ʒij.
M. L'Hôpital St. Louis (Paris).

58.—Lotion for Acute Eczema in Infants :—

℞ Lot. nigræ, ℥iv ;
Liq. calcis, ℥iv ;
Mucil. tragacanth, ʒj
M.

59.—An Application for Recent Ringworm :—

℞ Thymol, ʒss ;
Chloroformi, ʒij ;
Ol. olivæ, ad, ℥j ;
M.

To be applied night and morning.

The Practitioner.

60.—For Laryngeal Phthisis and Dysphagia :—

℞ Cocainæ hydrochloratis, gr. x ;
Acidi borici, gr. iv ;
Glycerini, ♏xv ;
Aq. destill, ad, ℥j.
M.

To be applied to the throat when necessary.

The Practitioner.

61.—A Local Application in Diphtheria :—

℞ Acid salicylatis, 3 parts.
Alcohol, 20 „
Resorcin, 2 „
Glycerini, 10 „
M.

The affected parts to be touched twice daily with the application.

B. Antonio.

62.—A Sedative Cough-Mixture in Phthisis :—

℞ Sodeiæ sulph., gr. iij ;
Liq. atropiæ sulph., ♏xij ;
Liq. strychniæ, ʒj ;
Syr. tolutani, ℥iss ;
Infus. rosa acid, ad. ℥vj.

M. A tablespoonful in a wineglassful of water every four or six hours.

◆

Clinical Records.

SHEFFIELD GENERAL INFIRMARY.

Under the care of Mr. Arthur Jackson, M.R.C.S.,
Senior Surgeon, &c.

A. W., æt. 23, was admitted into the infirmary on January 27th, 1894. with a large pharyngeal polypus hanging down below the soft palate, and pushing it very much forwards. (a) She noticed that the nostril was blocked up soon after an attack of influenza rather more than two years ago. She could not get any air through her left nostril. She had difficulty in swallowing and talked thick, but the pain in her head continued to increase and became intense. It was not difficult to get a finger up to the top of the hard mass through the mouth, and the opinion formed was that it had a bony attachment. Chloroform having been administered an attempt was made to pass a wire *écraseur* through the left nostril but unsuccessfully. Then the *écraseur* was passed through the mouth round a portion of the tumour which was removed, leaving a much larger mass behind. This was seized with a pair of vulsellum forceps and removed without difficulty. On examination the tumour was found to consist of two portions intimately attached to each other, one evidently a gelatinous nasal polypus, and the other larger part of dense fibrous tissue. There was no bony attachment at all, and the fibrous portion was evidently kept in its position by its attachment to the gelatinous portion.

There was little or no bleeding, and the patient has done very well. There was no sign of the existence of a gelatinous polypus to be seen on examination of the nose.

(a) Specimen shown at the Sheffield Medico-Chirurgical Society, February 1st, 1894.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, Feb. 9th, 1894.

The President, Mr. J. W. Hulke, F.R.C.S., in the Chair.

ADJOURNED DISCUSSION ON NEPHRECTOMY FOR MALIGNANT TUMOUR IN AN INFANT.

Mr. **Bland Sutton**, in reopening the discussion, recapitulated the main facts of the case, viz., the successful removal of a renal tumour including its capsule from a child 23 months old, the tumour consisting mainly of epithelial tubules embedded in a rich stroma composed of young connective tissue, the child being still alive, fourteen months after the operation. He pointed out that a careful analysis of reported operations for renal sarcomata in infants showed that more than one-half succumbed to the operation and, more than this, that the lives of the survivors was rarely prolonged beyond a year, the longest being eighteen months, and of this there were only three instances. If the tumour removed by the author stood by itself it would probably be called a sarcoma, but a broad survey of sarcomata in children showed that they were characterised by peculiar kinds of tissue. Of these the most remarkable were large spindle-cells, transversely striated, resembling on section voluntary muscular fibres. Another form was cubical epithelium arranged as tubules or as solid columns. The presence of tubules was an almost constant feature of sarcomata arising in glands and was due to enlargement of the tubular elements. In the renal sarcoma of infants these epithelial structures might be very abundant or almost absent. In the latter condition the tumour was very prone to contain striated spindle-cells in great abundance. It had occurred to him that tumours with abundant tubulæ might be less malignant than those in which striated spindles abounded, but further investigation did not support this view. There was nothing in fact in the histological characteristics of these tumours permitting anyone to distinguish between malignancy and non-malignancy. Abbe had recorded the case of a child whose tumour consisted almost entirely of the pseudo-muscle fibres, and a second case in which the histological characters were almost identical with those observed in the author's case. Both the children recovered from the operation and lived eighteen and fourteen months respectively, so that it was obviously impossible to venture on a prognosis. The idea therefore that the non-recurrence of the tumour in the author's case had any connection with its histological structure fell to the ground. Turning to the surgical aspect of the question, he pointed out that in Abbe's case the tumours were removed by simple enucleation out of the capsule so that the removal of the capsule as an explanation of the immunity in the author's case must also be discarded. Considering the risks inseparable from the removal of these tumours, along with the capsule, in infants, he pointed out that they were increased two or three times when the capsule was removed as well. He doubted, therefore, whether it was desirable to attempt to get away the capsule. He thought, moreover, that there was no more reason to bring the ureter outside than there was to bring the tied end of a Fallopian tube outside, and he suggested that the tied ureter might very well be left to take care of itself. Passing on the consideration of the surgical principles involved, he pointed out that surgeons removed tumours (1) when there was pain, (2) when their presence gave rise to inconvenience, and (3) when their existence threatened life. These renal sarcomata in children were painless, and could hardly be said to give rise to inconvenience. Though they certainly threatened life he thought that, considering that their chances of prolonging life by operation were so very remote and the immediate risks of the operation so great, even in the hands of the most skilful operators, surgeons ought to deliberate before undertaking their removal, in fact he was of opinion that they had best be left alone.

Mr. **Alban Doran** referred to a paper read by Dr. Spencer before the Obstetrical Society some years ago in which that author had directed attention to the results of the examination of still-born children or infants born so organically defective that they soon died. He had in this connection pointed out the extreme frequency of hæmorrhage into the solid viscera, particularly into the kidney. Out of 120 still-born infants, 38 had hæmorrhage in or around the kidney; in 22, the hæmorrhage in the capsule of the kidney, and in a few, partly within and partly without the substance of the kidney. There was good reason to believe that these hæmorrhages were often intra-uterine, and he urged that they might prove the origin of sarcomatous growths and malignant tumours. The observations as to the situation of the hæmorrhages held good in respect of the situation of these tumours. Some of them were separate from the kidney substance, sometimes they replaced the kidney. He had seen the infant in question, and was in favour of the operation, and in this case the end must be held to have justified the means.

Mr. **Targett** mentioned that sections had only been made from one side of the growth, and these showed it to be largely composed of tubules.

The **President** alluded to a case which he had brought before the Pathological Society in November, 1860, in which a large tumour of the testicle had been removed and showed structures which very closely simulated striped muscular fibre.

Mr. **Malcolm**, in reply, said that he saw no reason why these tumours should not be dealt with on ordinary surgical principles, and the removal of the investing membrane would be thought indispensable in operating on sarcoma elsewhere. He did not believe, moreover, that it added much risk to remove the capsule at the same time. He pointed out that the end of the Fallopian tube was surrounded by peritoneum, which was not the case with the end of the ureter, the former moreover, was a tissue that most readily underwent repair.

Mr. **Arbuthnot Lane** read an account of a case of

MULTIPLE EPITHELIOMATOUS FORMATIONS OCCURRING AT DIFFERENT PERIODS IN A PATIENT SUFFERING FROM PSORIASIS FROM INFANCY,

and who had for thirty years been treated with Fowler's solution. The man when first seen by him was sixty years of age, and had on the back of his forearm an ulcerating epitheliomatous area nearly two inches in diameter. This was said to have commenced as a single nodule about which at a later period three distinct nodules formed. As time went on the increase in the size of the four plaques resulted in their union, and the formation of a single one. There was no glandular enlargement. The ulcer was removed in April, 1892. At that time he was free from any eruption and made no mention of it. Mr. Lane saw him again in March, 1893, when he found three separate epithelial growths ulcerating in their centre, and placed on the scrotum and perinæum. They were in the same vertical antero-posterior plane, and were separated from one another by intervals of one and two inches respectively. These were removed and examined microscopically. At this time he was covered by the eruption and gave the history already mentioned. He was directed to give up his arsenic and to return if anything suspicious was observed. Not appearing he was written for in December, 1893, when two raised plaques a quarter of an inch in diameter and placed at the same level in the scrotum an inch apart, and an inch in front of the most anteriorly placed of those last removed. They were perfectly smooth. On being cut out and examined microscopically they were found to be small epitheliomas. Again on January 22nd, 1894, two more typical little epitheliomas were removed from the scrotum, one being in the scar of one that had been very freely removed on the last occasion. This patient has up to the present date had eleven separate foci of malignant growth, four appearing on the forearm, and seven on the scrotum and perinæum, and on only one of these, namely, one by the anus, was there any suspicion of the growth having taken place in a patch of psoriasis. There is no reason to suppose that the formation of these growths will cease, and they must be looked for and removed as they appear.

Mr. **Jonathan Hutchinson** asked whether any other conditions preceded the development of the epitheliomatous growths, whether in fact anything of the nature of a corn formed before the epithelial process was declared? He asked particularly whether anything peculiar was noticed in the palms and soles of the patient. In most of the cases of this kind that had come under his observation the palms and soles had been affected in a very peculiar way, a number of corneal indurations forming, and this might be taken as an indication that the epitheliomatous process was setting in. In one case, however, the epitheliomatous process started from on one side of the abdomen. He had had no further case since he published his paper on the subject which he could venture to adduce as conclusive. He, therefore, always left off the use of arsenic as soon as any disturbance became manifest in the palms and soles, even if the disturbance only affected sensation.

The **President** said that some years ago he instituted a series of inquiries among the workers in the arsenical mines of Cornwall, thinking that if anything of the kind was really caused by arsenic, it would assuredly be among these men that they would be met with. He had, however, been unable to discover a single instance in support of this hypothesis, in spite of the fact that the local irritation of the arsenic was very severe, and the general condition of the workers most pitiable. He had had a case of multiple epithelioma, but this was not due to arsenic, for it started from a simple wart.

Mr. **Lane**, in reply, said that the first growth appeared in the midst of apparently healthy skin.

Mr. **Arbuthnot Lane** read the notes of a case of

GENERAL ACUTE SUPPURATIVE PERITONITIS DUE TO APPENDICITIS,

which had been under the care of Dr. Shute, of Northfleet, and on which he had operated. E. B., æt. 18, had three years previously an attack of acute abdominal pain which confined him to bed for a week. It was regarded by the medical attendant as inflammation of the bowels. A year ago he had a similar attack which kept him in bed for four days. On Sept. 1, 1893, and on the day following, he suffered from slight pain in the stomach, but did not feel at all ill. He attended to his duties, took his food well, and went for a long walk in the evening of the second day. Between six and seven on the morning of the 3rd inst. he awoke with diffused abdominal pain, which persisted and increased in severity. His bowels were opened freely, but as the pain continued he took a dose of castor oil. Dr. Shute saw him for the first time at two o'clock the same day. He found him in great pain, with a rigid and tender abdomen, and with cold extremities. He had vomited once after the castor oil. Fomentations were applied, and morphia was freely administered. On Sept. 4 the patient was worse, and on the following day, as his symptoms had increased in severity, Mr. Lane was asked to see him with a view of interfering surgically. He saw him with Drs. Shute and Crook, and concurred in their diagnosis, namely, that an abscess had formed about the appendix, and that the very acute peritonitis had resulted from its rupture on the morning of the 3rd inst. Owing to the extreme rigidity of the abdominal muscles and the associated tenderness no examination by palpation was possible. In spite of the very serious condition of the patient, and the almost universal failure of such operations under these conditions it was decided to interfere. After the administration of morphia and chloroform, the rigidity of the abdominal muscles remaining while the patient was in a condition of complete anæsthesia, a medium incision was made. A small quantity of creamy pus oozed out between the edges of the peritoneum. On exploring the abdomen all the viscera were seen to be intensely injected, to move freely upon one another, and to be covered by a thin layer of pus which was most obvious where the viscera came into apposition. The inflammation seemed to be equally intense everywhere and there seemed no adhesions. On examining the right iliac fossa a very large appendix was found lying immediately internal to the anterior superior spine. It was exposed by an incision made over it, when it was found to be about as large as a thumb, intensely hard and congested, and to form part of a wall of a localised abscess cavity with adjacent viscera. It was evident that the general peritonitis resulted from the rupture of this abscess cavity. The appendix was removed and was found to be intact. It had no smell whatever, neither had the pus in its immediate vicinity. The advisability of washing out the peritoneal cavity was discussed, and it was considered that no benefit would be derived from it, since irrigation to be sufficiently thorough to wash away even a proportion of the pus which was so uniformly distributed in a fluid state and in very small quantity, would, owing partly to its universal diffusion and partly to the extremely rigid condition of the abdominal muscles, only result in the death of the patient on the table. Again there was no reason to suppose that if all the pus could be removed the intense inflammation of the peritoneum would subside. It was also felt that the introduction of drainage tubes or of tampons of gauze would serve no useful purpose but would rather add to the patient's risks, so it was determined to close the wounds, to keep the patient under morphia, and to feed by the rectum. The patient improved slowly but steadily after the operation, so that by the 15th inst. when the stitches were removed he had lost his pain and the abdominal muscles moved freely during respiration. The chief points of interest about the case was the fact that a most acute general suppurative peritonitis due to the bursting of the wall of an abscess cavity about the appendix recovered under medical treatment only. The operation could have had no beneficial effect upon the existing peritonitis. That the removal of the intensely inflamed appendix was most advantageous to the patient was obvious. How far its continued presence in the abdomen would have affected the result of the existing peritonitis cannot be determined with any certainty, though the improvement that followed almost at once upon its removal would lead me to suppose that it was acting as a progressive source of infection to the peritoneal cavity. Besides that, the condition of the appendix was such as to suggest it might become gangrenous. The operation, therefore, in all reasonable probability saved the patient's life and freed him from the risk of subsequent attacks.

Mr. **Malcolm** said the author seemed to infer that the pus had been absorbed, but he did not see how this could have taken place.

Mr. **Barker** said he had operated in two similar cases, and in neither had he drained, yet both had got well. He did not actually get hold of the appendices in his cases, but there was general inflammation of the peritoneal cavity, and over a pint of pus was evacuated in each case. He thought that in many of these cases drainage might be dispensed with with advantage not only in tubercular cases, but in others. It would suffice for them to evacuate all the pus they could and leave the rest to the absorptive powers of the peritoneum. He flushed in both his cases, but he did not suppose he had flushed out all the pus. It must, of course, be borne in mind that there were cases in which drainage could not safely be dispensed with.

Mr. **Howard Marsh** observed that the case seemed to have been of some standing, and it was, therefore, difficult to conceive that suppurative peritonitis should not have occurred. They all knew the danger of a prolonged operation, and possibly it might be best to leave these cases alone, for prolonged washing out was probably more than many a patient could stand.

Mr. **Bowlby** asked if the author had evacuated much pus?

Mr. **Waterhouse** mentioned the case of a woman who had been suffering for four days from intestinal obstruction; the abdomen was rigid, and diagnosis was impossible, the patient appearing to be *in extremis*. He laid open the abdomen and a large quantity of sero-pus escaped. He searched for the source of the exudation, and not finding any he closed the abdomen, fully expecting that the patient would shortly die. She, however, recovered.

Mr. **Gould** asked to what extent the author supposed that the subsequent course of the case was influenced by the course taken by the author?

Mr. **Lane**, in reply, said it was a typical case of suppurative peritonitis. He had seen many such, but this was the first he had saved. In Mr. Barker's cases the remaining pus must have been absorbed. He remarked on the fact that he had not smelt the appendix while removing it in this case, and this encouraged him to hope for a favourable result. He did not think that the operation materially influenced the progress towards recovery.

Mr. **John R. Lunn** on a case of

FUNGATING GROWTH OF PENIS (EPITHELIOMA ?)

George I—, æt. 31, a porter, admitted into St. Marylebone Infirmary, August, 1892. He had been under treatment for a growth on his penis since January 1891, at different hospitals and infirmaries, but had not got quite well. Amputation was advised at one hospital, but the patient refused. On admission under my care the patient had some old doubtful signs of phthisis at his right apex. There was a mass of unhealthy granulations all round the corona of his penis and covering his glans penis, there was a large raw granulating surface on the dorsum of his penis near the root, and several small nodules on the scrotum (near where it joins the skin of the penis on the under surface). Some of the nodules were breaking down, leaving small painful ulcers, the nodules were due to the affection of the sebaceous follicles and there were also present some doubtful amygloid glands in both groins. The patient was suffering intense pain, especially on passing urine, and the surfaces of the glans-penis were raw and covered with small granulations. These were curetted under an anæsthetic several times but did not improve much, and the ulcers rapidly spread at their edges. Morphia was given often to relieve pain. Iodoform and cocaine were applied freely and a mixture of iodide of potassum with mercury was given internally. Continuous irrigation was tried for two nights and days, but was discontinued as the patient complained of such intense pain, though the effect on his penis was very marked and the patient rendered much more comfortable, though he still complained of intense pain on passing urine and when the penis was dressed. About the end of November the patient's health began to fail, his temperature to rise, his life seemed a misery, and he begged for something to be done, so it was decided as a last resource to amputate the penis. This was done by my colleague, Dr. Nix, Jan. 25th, 1893. A few days after the operation the patient began to suffer from swollen glands under his jaw on both sides, and his temperature went up to 102° F.; also a gland near Poupart's ligament (on the inner side) became much enlarged. The suppurating glands under the jaw were incised and some bad teeth were removed, but the condition under the jaw did not improve, and so on March 2nd, the glands were scraped and the glands in the groin were removed. The glands under the jaw were thought to be due to salivation from the large doses of mercury he had been taking. He was discharged cured in June 1893. Mr. Targett kindly examined the penis that was removed and sent me the following account. The extremity of the organ was converted into an oval lobulated tumour, two inches in its chief diameters. The pigmental integuments at the margin are raised and undermined, and near the base of the tumour several white tubercles are seen protruding through the skin. On the reverse of the preparation, the urethra had been laid open, its lining membrane was much ulcerated and nodular, the glans penis being indistinguishable. The careful sections taken from the edge of the front are composed of cells and large round nuclei and numerous capillary vessels, as in granulating tissue, but sections from inguinal glands contain suspicious nodules of epithelial cells, the sections do not seem to show any evidence of tubercle.

Mr. J. **Hutchinson** agreed, as having seen the case, that the diagnosis was one of great uncertainty. He himself was inclined to think it was syphilitic in spite of the fact that no secondary symptoms had been observed, though after all this was not so remarkable seeing that the patient had been strongly mercurialised. He pointed out that the prolonged bath had not been given a fair trial, only having been persisted in for forty-eight hours instead of ten days or a fortnight. He would have given opium to the patient to calm his impatience. The only thing to do was to keep the patient under observation, and see whether he ultimately developed other syphilitic manifestations. He referred to the case of a gentleman with similar ulcerations under the eyelids which had resisted all treatment for a year. In this case there were no secondary symptoms.

Mr. **Gould** asked whether the assertion that a hard chancre had developed after a soft one had been confirmed by medical evidence? He pointed out that the interval was long enough to allow of the man to have had secondary symptoms and disappeared. He pointed out that the granulations were analogous to the fungating syphilitic tertiary sore of the leg, which were also very resistant to anti-syphilitic remedies.

The **President** referred to the case of a gentleman who had a fungating sore on the instep, which looked remarkably like an epithelioma. Small masses could be seen on the leg as far up as the knee. Anti-syphilitic treatment had been tried, not because there was any history of syphilitis, but "just to try." The patient might have inherited syphilis from his father, for his two sisters presented unmistakable traces of having had interstitial keratitis while children. He had ultimately to amputate the leg. Later, the patient developed a swelling of the forearm which discharged gummatous masses, and he died, with similar manifestations in the neighbourhood of the hip.

Mr. **Lunn** said the diagnosis of hard chancre was confirmed by the service doctor. The patient had had no secondary symptoms, but he promised to keep him under observation.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, January 19th.

The President, Dr. **Walter G. Smith**, in the Chair.

CANCRUM ORIS IN TYPHOID FEVER.

Dr. H. T. **Bewley** described the case of a boy, æt. 14, who was attacked very severely by typhoid fever. On the 41st day of the disease a black patch was noticed inside the right cheek, and two days after another black patch was observed inside the left cheek. The latter soon healed, but the former was accompanied by much hardness and swelling of the cheek, and increased till it involved the skin. Then the gangrene ceased to spread and the slough rapidly separated. The boy during this process was very weak, but was given large quantities of nourishment and stimulants—12 oz. of whisky every 24 hours for 10 days—and seemed to derive much benefit therefrom. The slough was very large, and when it came away left an opening through the cheek of the size of a shilling, and a large cavity inside the cheek extending from near the angle of the lips to the ascending ramus of the jaw. The boy, however, made a good recovery, and the opening through the cheek closed completely in about six weeks. No contraction has yet occurred in the tissues. The stench, which had been very bad, Dr. Bewley thought, was most successfully kept down with local application of creolin and of eucalyptus oil. Dr. Bewley called attention to the rarity of cancrum oris in typhoid fever, to the high mortality which occurs in it, and to the fact that this case did extremely well without any surgical interference.

Dr. **Pollock** mentioned a case of typhoid in which he had seen inflammation and sloughing of an entire submaxillary gland.

Dr. J. W. **Moore** said that during 13 years' experience as visiting physician at Cork Street Fever Hospital he had seen only four cases of cancrum oris—two following measles and two following typhus. Murchison, in an experience of 5,800 cases of typhoid fever, had seen it occur in it only once. Dr. Moore recommended that the mouth should be rendered as aseptic as possible and kept so. The teeth might be cleansed with a paste composed of eucalyptus oil, liquefied carbolic acid and precipitated chalk, and the mouth might then be rinsed out with an antiseptic fluid.

Dr. **Doyle** said he had treated two cases of cancrum oris last year. He did not know whether they were recovering from fever, but he found them on admission to hospital with very decayed teeth. These he extracted and applied to the gangrenous surface in one of the cases hydrochloric acid and in the other nitric acid. The subsequent treatment consisted in cleansing the mouth with a large throat brush and spraying the cavity of the mouth. He also sprayed the interior of the nose and the back of the throat. As medicine he gave small doses of tr. opii and found them very beneficial.

Dr. **Finny** said he had only seen the teeth and gums affected by extension from the cheek. He pointed out that the disease always began in the cheek opposite the first molar tooth.

Dr. **Boyd** narrated an account of the treatment pursued in one of the children's hospitals in New York, where an epidemic of cancrum oris broke out. There were forty cases, and the mortality was only four or five, Subnitrate of bismuth was applied locally. He remarked that the disease had become much less frequent since mercury had been less freely used. He thought that the extensive ulceration in the bowel in typhoid fever allowed of the absorption of the poisonous products of bacteria present in the contents of the intestines. This might have something to do with the extensive suppuration which occurred in Dr. Bewley's case.

Dr. **Little** drew attention to the benefit resulting from the administration of stimulants in this case. He considered that the whole question of stimulants required revision. In some cases patients get well in which they are freely given, but they would have done better without them, whilst in others they would have died if they had not got them. He had seen alcohol do good in cases of pyæmia and septicæmia.

Dr. **Dawson** mentioned a case of a boy, æt. 6, recovering from measles, who was well nourished, but was attacked with cancrum oris first in the left cheek and then in the right. The greater part of his left cheek was destroyed, and a portion of the alveolar process of the jaw exposed. His right cheek was perforated with a hole of about the size of a sixpence. The child recovered; the hole in his right cheek was obliterated; and the opening in the left cheek was much diminished without any operative interference. To allay the foul odour dilute sulphurous acid was sprayed into the mouth.

Dr. **Davis** suggested that the opening of the parotid duct being situated near the position at which the ulcerations usually occurred, it was possible that it might afford a nidus for micro-organisms.

The **President** said that the local complications occurring in the mouth in acute fever were of three sorts:—1. Severe ulceration. 2. Acute peritonitis. 3. The gangrenous inflammation styled "cancrum oris." Dr. Bewley's case was interesting in that it attacked an older patient than is usual, and that the disease occurred after typhoid fever. In favour of there being a specific cause for the disease we have—(1) its rarity, (2) the definite symptoms and signs, and (3) the constancy of the appearances presented. The foul smell is not a constant factor. In a case lately treated in Sir P. Dun's Hospital there was absolutely no odour. It is a matter of note the quantity of stimulants taken by this boy in a short time. Alcohol, as it is oxidised into carbonic acid and water, is capable of being a source of energy to the body and thus a good—using this word in its widest sense. When more than a certain quantity is taken, part of it circulates unchanged in the body and is excreted as such. To this portion present in the tissues as alcohol might be referred—(1) its antipyretic properties, (2) its antiseptic properties, and (3) its action on the leucocytes.

Dr. **Bewley**, in reply, stated that this boy had a very considerable quantity of opium throughout his whole illness. His teeth were not at all affected. He could give no reason why the disease began opposite the first molar tooth. He thought the opening of the parotid duct had nothing to do with it, because in his case the duct was not opened, and no salivary fistula resulted. As regards the stench, it came from the dead slough, and when it was removed the stench ceased.

CASE OF ASSOCIATED PARALYSIS OF THE RIGHT PORTIO DURA AND PNEUMOGASTRIC NERVES.

Dr. J. W. **Moore** read the notes of this case. The patient was a girl, æt. 13, who was subject to nasal catarrh. An attack of suppurative inflammation in the right sphenoidal sinus was suddenly complicated with right facial palsy, associated with paralytic dysphagia, necessitating feeding by the bowel exclusively, and after a fortnight by the œsophageal tube. These paralyses were ushered in by serious symptoms, more than suspicious of mischief at the base of the brain—giddiness, headache, uncontrollable vomiting, chills followed by high fever. These passed off in a few days, but foul-smelling discharge continued to flow from the posterior nares intermittently for several weeks, and the breath was at times very fœtid. The larynx also was paralysed on the right side. Inflammation seemed to have extended from the right sphenoidal sinus, backwards towards the foramen magnum, behind the dura mater, in such a way as to cause compression of the right facial and pneumogastric nerves, either indirectly at their points of origin, or directly in their course (from their points of emergence on the surface of the brain) to the internal auditory meatus in the case of the facial, of the posterior lacerated or jugular foramen in that of the pneumogastric nerve.

Dr. **Parsons** wished to ask what was the condition of the patient's tasting powers. Could the paralysis of the 7th nerve be a mere coincidence. It was very odd that the 6th nerve was not affected if the patient suffered from basal meningitis, considering the frequency with which it is affected. As regards the path by which sensory impulses of the taste reached the brain, physiologists and clinical physicians were not yet agreed.

Dr. R. A. **Hayes** considered that it was pretty evident that there was an empyema of the sphenoidal air sinus. The pus, however, found free exit and did not produce pressure symptoms. An extension of inflammation by continuity of tissue, remembering the great thinness of part of the wall of the sinus, might account in the main for the symptoms.

Dr. **Davis** thought that the nerve affected might have been the accessory portion of the spinal accessory.

Dr. **Finny** thought that the simplest explanation was an abscess in the upper posterior part of the pharynx, and that it engaged the 7th nerve close to its exit from the stylo-mastoid foramen.

Dr. J. W. **Moore**, in reply, stated that both the motor and taste functions of the patient's tongue were perfect. There was no ear lesion and no hyperacuteness of hearing. As regards Dr. Finny's view, it does not seem to fully account for the first four days of the illness when the patient suffered from giddiness, vomiting, and severe pain in her head.

The Section then adjourned.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, Feb. 7th.

Dr. T. S. **Clouston**, President, in the Chair.

DISCUSSION ON INTERCRANIAL SURGERY.

Professor Annandale, who opened the discussion, said that he would make his remarks as practical as possible, and alluded to the recent advances made in cerebral surgery permitted by the adoption of antiseptics, and by the perfection of localisation. He then divided his subject into seven divisions, which he discussed *seriatim*.

1. *Diagnostic Incisions.*—These should always be made if there were symptoms of brain pressure of doubtful cause and unrelieved by medical treatment, and again in cases of great pain in the head with no discoverable cause. In one such case he had trephined the skull, incised the dura mater, found nothing, but benefited the case presumably by relieving tension.

2. *Intercranial Inflammation and Suppuration.*—If following traumatism, speedy operation was advisable. In one case he had had suppuration followed the necrosis of the injured bone over the left motor area, caused epilepsy, but was entirely relieved by operation. It should be remembered, however, that such inflammation sometimes occurred on the opposite side of the brain to that injured. Middle-ear disease was often followed by symptoms due to meningitic inflammation or to cerebral abscess, in some of which cases, nevertheless, the ear disease which had caused the cerebral lesion gave rise to no symptoms. In all these cases free exit should be given to the pus. In idiopathic inflammations, such as those due to tubercular deposits, whether the abscess be localised or the symptoms general, it always gave a chance of relief to operate.

3. *Hæmorrhage.*—In cases of hæmorrhage due to traumatism it was the duty of the surgeon to operate. One very curious case which he had seen resulted in the following way: Some soldiers were sky-larking, and one of them received a thrust on the head with an umbrella, one of the spokes of which penetrated the skull, punctured the middle cerebral artery, and caused death very speedily. Again, it was advisable to operate on the opposite side to the injured part, if nothing had been founed there on trephining. In some cases he would advocate operation in non-traumatic hæmorrhage with a view of relieving tension.

4. *Epilepsy.*—The fits when following on injuries might be caused by the pressure of a foreign body itself or to the inflammation set up by it; the removal of the foreign

body was advisable. Cysts should be drained after opening. In syphilitic and idiopathic cases no operative treatment was indicated, though if caught early enough it might prove of some use. In developmental cases, if sclerosis had already occurred, no good could ensue; otherwise might prove beneficial.

5. *Intercranial Tumours.*—In syphilitic cases an operation might be undertaken to relieve pressure; sometimes it was followed by a shrinking of the tumour. Tumours involving the motor areas had been successfully removed by him. In one case the tumour proved to be as large as a cricket ball.

6. *Microcephalus and Hydrocephalus.*—The first of these conditions was amenable to operative interference, the second not.

7. *Insanity.*—Two per cent. of the cases were due to injury, and if these were operated on shortly after their occurrence good might be done. The prospect of doing anything of value in general paralysis seemed small.

Professor Grainger Stewart contributed details of several cases in which he had asked a surgeon to operate. Among these were cases of meningitis, trephined without relief; tumour of the cerebellum, treated with temporary alleviation of the symptoms; glioma of one of the hemispheres, operated on unsuccessfully. In another case epileptic fits, both petit and grand mal, with great pain, followed a blow on the head, and marked optic neuritis supervened. Operation cured the fits and the pain, but on death two years after nothing could be found in the brain at the autopsy to account for the symptoms. In conclusion, he advocated free operative interference if medicinal means had failed, if only to relieve pressure.

Dr. McBride considered the subject from the point of the aurist. He said that the three chief intercranial results of ear disease were meningitis, phlebitis, and abscess, their frequency being in that order, and proceeded to discuss the early symptoms and indications of their appearance.

Dr. Berry discussed the occurrence of optic neuritis, which, he said, never occurred except with tumours or abscess of the brain, ophthalmic paralysis, and hemianopsia in brain lesions.

Dr. Joseph Bell had operated in one case of microcephalus with a fair result, although the child's intelligence did not seem to be much increased.

Drs. Carmichael, Smart, and Bow also spoke.

◆

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, Feb. 1st.

The President, Mr. George Eastes, in the Chair.

The President read notes of a case where a pessary in the shape of a hollow sphere of wood 2¼ inches in diameter had been retained in the vagina for many months, and had partially enclosed the uterus, rendering it almost gangrenous.

Mr. F. Bowreman Jessett showed two specimens, one of carcinoma uteri, the other of multiple fibroma of the uterus, which he had successfully removed per vaginam.

Dr. Gow read a paper on

EIGHT CASES OF VAGINAL HYSTERECTOMY FOR CANCER.

After drawing attention to the fact that vaginal hysterectomy for cancer was not regarded with much favour in this country, he proceeded to read notes of eight cases in which he had performed the operation. All the patients recovered from the operation and were able to return to their household duties, and five of them were known to be alive at the present time. Six of the patients were suffering from carcinoma of the cervical canal, one from carcinoma of the body of the uterus, and one from sarcoma of the body of the uterus. Of the eight patients, two had died from recurrence within twelve months of the operation, one had been lost sight of, one had remained free for two years and eleven months, and one for twelve and a half months. The two last mentioned patients were both well at the time of the reading of the paper. The three remaining patients had been operated on during the last twelve months, and therefore sufficient time had not elapsed to allow conclusions to be drawn as to the ultimate result. He believed that the mortality was sufficiently low and the results sufficiently good, to render the operation worthy of confidence in suitable cases. In discussing the technique of the operation he upheld the use of silk ligatures in preference to clamps, as being the safer method of securing the broad ligaments. He did not think it was necessary to make any attempt to close the wound in the vaginal vault or to stitch the peritoneum to the vagina. After removal of the uterus a long strip of iodoform gauze should be introduced into the vagina and left undisturbed for from five to seven days. He advocated complete extirpation of the uterus in cases of cancer involving the whole length of the cervical canal as well as in cases of malignant disease of the uterine body. In cases of squamous-celled epithelioma of the vaginal portion or of carcinoma involving the lowest part only of the mucous membrane of the cervical canal, he believed supra-vaginal amputation of the cervix to be indicated. Extensive operations were only justifiable when it appeared probable that all the disease could be removed.

Mr. F. Bowreman Jessett congratulated the author of the paper upon the success of his cases, and remarked, as more experience was gained, possibly it would be found that while certain forms of malignant disease of the uterus could be removed with great and perhaps permanent benefit to the patient, in others, especially the sarcomatous, or rapidly growing forms of carcinoma, would be better left alone, as his experience tallied with the results of Dr. Gow's cases, viz., that these forms of malignant disease rapidly returned. He (Mr. Jessett) was interested in the statistics given by Dr. Gow, but did not hear him refer to Dr. Lewer's cases or his own cases, twelve in number, which had been published. He had now done twenty cases with one death. He agreed with Dr. Gow that silk ligatures were preferable to catgut; if the ligatures applied to the ovarian arteries were cut short they became encysted in the same manner as the ligature round an ovarian pedicle; while the outer ligatures usually came away in about ten days to a fortnight, sometimes later. He was much interested in the case which had secondary deposits on the abdomen causing pressure on and obstruction of the pylorus with accompanying dilatation of the stomach. He had had one similar case, the dilatation commencing some months after the operation. This patient died, but unfortunately no post-mortem was allowed. He always introduced a glass drainage tube for the first twenty-four or forty-eight hours, and packed the vagina with iodoform gauze.

Dr. Herbert Spencer bore testimony to the excellence of the paper. He would briefly allude to four points: one was that, in his opinion, catgut was preferable to silk for ligature of the broad ligament in vaginal operations; secondly, the removal of the ovaries in vaginal hysterectomy was not always necessary, and was followed in some cases by the total loss of sexual passion and by other troubles; thirdly, the diagnosis of cancer by the microscope was sometimes extremely difficult; fourthly, in considering the relative mortality of vaginal hysterectomy and supra-vaginal amputation (which statistics still showed to be in favour of the latter), he would remind the Society that, after hysterectomy, small intestine often adhered to the scar and became rapidly involved, when recurrence took place and death (from intestinal obstruction) occurred much sooner than it would have done had the body of the uterus been left.

Dr. Herman agreed with Dr. Gow both as to the diminished mortality of vaginal hysterectomy as compared with that at the time of the publications to which he had alluded, and as to the advantages of hysterectomy over supra-vaginal amputation of the cervix for cases of cancer beginning in the cervical canal. For cancer beginning in the vaginal portion amputation of the cervix was enough.

Dr. A. Routh and Dr. Handfield Jones also took part in the discussion.

◆

LIVERPOOL MEDICAL SOCIETY.

Meeting held Thursday, February 1st.

The President, Mr. C. Puzey, in the chair.

Pathological Specimens.

Dr. Abram showed (1) carcinoma of the gall-bladder with diffuse infiltration of liver. (2) Healing typhoid ulcers from a case without temperature, diarrhœa, or spots.

Dr. Davies: Hydrocephalic fœtus, one of twins.

Pyo-nephrosis.—Mr. Larkin showed two cases he had operated on for pyo-nephrosis, one a woman, æt. 24, with a ten years history in whom the disease, though apparently tubercular, seemed quite localised to the kidney. In her he had completely removed the diseased organ which was converted into a large thin walled cyst holding several pints of curdy pus. She is quite well 9 months after the nephrectomy. The other case was a man, æt. 28, who commenced with tubercular cystitis, then prostatitis, tubercular pyelitis and nephritis. He also had some dulness and flattening over the apex of the right lung. Mr. Larkin scraped out the abscesses in the kidney, washed out the pelvis and ureter, scraped out the prostate, and drained. He was shown (15 months after operation) well and hearty, weighing 10 stone, whereas he was under 8 when operated on. There is some thickening about the right epididymis which, however, does not increase.

Warty Growths.—Mr. Andrew Stewart showed a boy, æt. 9, suffering from warty patches on base of fore-fingers, elbows, knees, palms of hands, and tips of some fingers. Three years ago he had measles, and about three months afterwards the sores began to appear as red swellings. Mr. Stewart left the diagnosis open.

Mr. Rushton Parker thought it a case of lupus, or at any rate a lupoid disease of the skin, and he would treat it by scraping.

Dr. Barendt thought it a case of lupus verracosus, and recommended the application of salicylic acid plaster with creosote to the various patches, and then the application of powerful caustic to destroy the nodules.

Cancer of the Cervix Uteri.—Dr. Grimsdale read notes of a case and showed a specimen of cancer of the cervix uteri co-existing with a three months pregnancy, in a women, æt. 34. The uterus and its contents were removed through the vagina. The woman made a good recovery, and now, 8 months after operation, remains quite well.

Mr. Murray read a paper on the

TREATMENT OF CROOKED LEGS IN CHILDREN.

His remarks referred to children under 4 years of age, and he strongly advocated the immediate straightening of the crooked bones rather than the more gradual method by splints alone. In 1888 the late Mr. R. Pughe introduced this method at the Children's Infirmary, and the results have proved so satisfactory that of recent years there has been a large increase in the number of children brought to the Infirmary to have their legs straightened, as the following figures taken from the records of the hospital show. In 1888 Mr. Pughe straightened 30 legs and in 1893 Mr. Murray straightened 311, the total number since 1888 being 641. These figures include both knock-knees and bow-legs. Though he believed many surgeons practice osteoclasis for curved tibia, comparatively few do so for knock-knee, the objection, it is said, being that in doing so you produce a separation of the lower epiphysis of the femur. Mr. Murray has several times performed the operation on one side only, and examined the legs 18 months afterwards and found no difference in the length of the limbs, and further, he has made it a practice to examine carefully for the seat of fracture and find it takes place fully an inch above the epiphyseal line, his hands being the only osteo-chart he has ever used, the above figures refer only to children under 4 years of age. There has been no single mishap in the whole series.

Drs. Rawdon, R. Parker, R. Jones, Thel. Thomas, Puzey, Carter, Logan, and Alexander entered into the discussion.

◆

CATHOLIC UNIVERSITY MEDICAL SCHOOL MEDICAL AND SCIENTIFIC SOCIETY.

Meeting held Monday, January 29th.

Dr. A. Roche, Vice-President, in the Chair.

CASE OF FATAL PERITONITIS WITH TYPICAL TYPHOID LESION.

Dr. McWeeney showed portions of the small intestine of a boy who had died a few weeks previously from peritonitis at the Mater Misericordiæ Hospital. The intestines showed every stage of the typical typhoid lesion, including the "shaven beard" appearance described by the French pathologists. The base of one of the ulcers showed a minute perforation no larger than a pin's head, the cause of the fatal peritonitis. Bacteriologically examined the peritoneal exudation was found to be an almost pure cultivation of the bacillus coli. Dr. McWeeney pointed out how in cases of peritonitis supervening in suspected criminal abortion the presence of the bacillus coli might prove a fact of considerable medico-legal importance as indicating that the peritonitis was of intestinal origin; whereas peritonitis following female pelvic trouble was always due to streptococci. He had himself met with cases of peritonitis due to bacillus coli without any anatomically demonstrable perforation of the gut. In the present case the mesenteric glands were examined bacteriologically, and the cultures yielded bacillus coli. The question as to the distinctions between the two organisms were then touched upon, and the speaker expressed himself as disinclined to place much value upon the potato and other culture-tests. He looked upon bacillus typhorus as a well marked variety of bacillus coli, due to differencc of environments. Bacillus coli being sapophytic, and bacillus typhosus having acclimatised itself to dwell within living structures. Allusion to fermentation tests was made, and specimens of the U-tubes employed were shown. The dilution of bacillus coli in samples of drinking-water he regarded as of importance quite equal to that of finding bacillus typhosus. The great hygienic importance of the subject was insisted on.

The Vice-President complimented Dr. McWeeney on his communication. He agreed with the importance of bacteriological examination of water, but was of opinion that the chemical should not be neglected. Both were necessary for any satisfactory decision.

Dr. Blaney mentioned the formation vapour test.

Dr. McWeeney in replying, agreed with the Chairman as to the importance of chemical analysis. He did not think that formation vapour would prove more useful than Parietti's test. He had found it possible to acclimatise non-typhoid bacteria to the acidified and carbolised broth, and on one occasion when he had pushed the dose of acid and phenol to a very considerable amount without inhibiting growth, he found he had obtained a pure culture of an enormous coccus, and no bacilli of any sort.

Dr. Joyce showed two interesting specimens of hydrocephalus.

The Vice-President, Dr. Blaney, and Dr. Coffey joined in the discussion.

Dr. Joyce replied.

Mr. Tevitt read an interesting paper on the treatment of cholera.

The Vice-President showed preventive, had done more than curative, medicine for cholera. He mentioned the subcutaneous injection of water in the stage of collapse as useful.

Dr. Potter said he had large experience of cholera in India. He agreed with the Vice-President as to the great value of prevention. He mentioned the use of the external application of heat.

Dr. Ordye Curran spoke, and the Society adjourned.

◆

France.

[FROM OUR OWN CORRESPONDENT.

PARIS, Feb. 10th.

Exothyropexia.

At the Académie de Médecine, M. Poncet, of Lyons, communicated a new and very curious method of treating goître, which he designated under the name of *exothryopexia.* This operation consists in enucleating the tumour from its attachments and fixing it externally so as to provoke atrophy. Fourteen times the speaker practised the operation and each time with success. The thyroid tumours had been in every case treated medically without any apparent result, and their volume was such as to warrant active interference. Five of the cases were characterised as parenchymatous, while the remaining nine were cystic. The former took about six weeks to become atrophied, and the latter some time longer. As soon as the thyroid gland had been exposed to the air a serous liquid was seen to ooze from its surface, the veins became turgid and in a short time the tumour assumed a black appearance. The day following, the veins commenced to diminish in calibre, and continued to do so each day until the eighth, when their obturation was complete. At the same time the wound became granular and the skin adhered strongly around the base. The cause of the atrophy itself was difficult to determine, but M. Poncet supposed that the operation interrupted the venous circulation of the thyroid body. Besides these local phenomena, certain well marked changes came over the general condition of the patient, the intellect got brighter and the vitality received a considerable impulsion. As to the goître itself, it either disappears definitely or undergoes two principal transformations resolving into a hard fibroid tumour, or into cysts. The operation is applicable to every variety of goître, vascular, parenchymatous, polycystic, large, small, retrosternal or cervical, &c. In conclusion, M. Poncet, who was listened to with much interest, said that perhaps Basedow's malady might also be benefited by exothyropexia.

Prolapsus of the Uterus.

The treatment of the above affection is still under discussion at the Société Chirurgicale. Last week M. Pozzi spoke at length on the subject and said that total vaginal hysterectomy was only exceptionally indicated in the treatment of prolapsus of the uterus, that is to say, only where it was impossible to maintain reduced the vagina and the uterus, by more simple operative means, such as resection of the walls of the vagina and the occlusion of the great portion of the outlet. Hysterectomy is entirely counter-indicated in women who have had no children, and in those suffering from cardiac, renal, or pulmonary affections.

M. Picqué thought that hysterectomy gave but problematic results in the cases of old women in whom the prolapsus occurred from the weakness and the laxity of the anatomical parts. Alquié-Alexander's operation —shortening of the round ligaments—should be preferred.

M. Chaput said he had tried all the methods proposed in the discussion and came to the conclusion that total vaginal hysterectomy should be abandoned for the treatment of prolapsus, that operative measures should be limited to supra-vaginal extirpation of the os of the uterus when necessary, with resection of the vaginal walls before and behind.

Germany.

[From our own Correspondent.]

Berlin, Feb. 9th.

The Treatment of Scleroderma.

At the last meeting of the Dermatological Society Hr. Schütte showed a man whose illness begun with pain in the knees and elbows, and with the formation of red painful rhagades. The disease progressed slowly over the lower extremities and the right arm, and diminished greatly the usefulness of the limbs. Several methods of treatment had only a passing effect. On admission the skin over the lower extremities and the buttocks was smooth, shining, hard, and firm; bright and dark pigmented spots were irregularly scattered about. The patient could scarcely move the limbs; he mounted the steps as if the knees were anchylosed. The temperature of the skin was lowered. The treatment consisted of lengthened sitz baths, with succeeding massage with five to ten per cent. salicylic vaseline. The salicylin was increased as improvement progressed. The patient gradually regained power of movement of the extremities. A small quantity of salicylic acid could be determined in the urine, so that some must have been absorbed through the skin. The favourable influence of such treatment had been previously demonstrated in the case of a female shown to the Society. In that case the improvement had been maintained.

The speaker also showed a little girl, æt. 10, in whom the method of treatment described had had good results. The case was, however, less convincing as the child had been treated as an out-patient, and electricity had been employed on account of facial hemiatrophy.

Hr. Lewin thought as regarded the result of treatment of scleroderma that the spontaneous variations in the complaint should be taken into account.

Hr. Lassar replied that the case showed the slowly progressing improvement was opposed to one independent of treatment.

Generalised Vaccinia.

Hr. Peter showed a boy, æt. 6, suffering from chronic eczema. When the child attended Hr. Lassar's Klinik in October last, his whole body was covered with pustules from the size of a pea to a linseed. If the general health had not been comparatively good one would have thought of small-pox. It appeared that on account of the eczema the boy had not been vaccinated. A fortnight before the outbreak of the disease a sister had been vaccinated with calf lymph. As the pustules formed both children had been bathed in the same water. It was probable that the boy had in this way become inoculated with humanised lymph, that the virus could easily find its way through the parts of skin denuded of its epidermis by the eczema. Hitherto most of the cases of accidental inoculation known had been the result of auto-inoculation by scratching. Only four cases of generalised vaccinia were recorded in literature. Three were published by Dieter.

Hr. Ledermann had observed a case in which the pustules were in parts in which scratching was impossible.

Diseases of Milkers.

Hr. G. Lewin showed a man who had been for many years engaged in milking, first in Switzerland, and now in Victoria Park. There was a fistulous ulcer on one finger from which hairs were extracted. The origin of the ulcer had not been explained. Both syphilis and tubercle could be excluded. On the inner side of the joint surfaces of both thumbs were hard prominent callosities. These must be considered as due to his occupation (Gewerbeaffektionen). The milker grasped the udder at the teat with the four fingers of the hand and extracted the milk by an up and down stroke against the strongly opposed thumb. If it was considered how hard the firmly-distended udder of the cow was, it was easy to understand how such callosities could be formed with many years of milking. According to the statement of the patient, a large number of milkers suffered in a similar way. He thought the symmetrical appearance of the marks on both hands could scarcely be accidental.

Hr. Ledermann then showed a case of

Syphilis of the Cord.

The patient, æt. 50, was syphilised in 1890. He was treated in the Charité by injections, and again in 1891, on account of a relapse, by potass. iodide. In 1892 he suffered from apparently non-specific iritis, for which iridectomy was performed. In 1893 a gummatous ulcer encircled the whole leg. This was treated in hospital with potass. iodide, and improved. In November last he was again admitted with recrudescence of the gummatous ulcer. Whilst under treatment he complained suddenly one evening that his left leg was asleep. Lancinating pains and a feeling of cold were present. The patient remarked that on trying to walk he staggered. Objectively there was increased patellar reflex of the left leg, functional disturbance of the bladder and rectum were present. The gait of the patient must be described as spastic. As the upper extremities were spared the spastic phenomena it was probably a case of disease of the spinal cord, that, bearing in mind the subjective and objective symptoms, was probably situated about the level of the last dorsal vertebra. Considerable improvement was brought about by specific treatment, about 140 grms. of potass. iodide were given altogether, and inunctions of 3 grms. of resorcin mercury daily; the spastic symptoms disappeared, and the knee phenomena became less pronounced. In reply to a question by Hr. Caspar, the speaker said that since the day before the function of the bladder had returned to some extent. In reply to another question by Hr. Isaac as to the nature of the affection, Hr. Ledermann said the disease probably affected the spinal meninges, with secondary compressive myelitis. He thought larger doses of mercury would have had no object, as stomatitis appeared with the inunction of only three grammes daily.

The First Cry.

At the meeting of the Hufeland Society of the 18th ult., Prof. Olshausen gave an address on this subject. He said that want of oxygen in the system could not be the sole cause of the cry. When the head was born, there were at first no spontaneous movements, either of respiratory or other muscles, but a bright red colour of the head changed in a few seconds into a bluish colour. That was natural, as the head emerged from the natural passages was no longer under pressure like the parts still within the genital canal, and this inequality produced a venous stasis in the head. When only 2 to three minutes elapsed before the birth of the trunk, this condition did not change. When this took place, the first inspiration followed in a few seconds, and then an expiration, accompanied by a loud cry, took place. However long the thorax was in following the head, no inspiration took place till that occurred, *i.e.*, if the period between the two was not longer than from 2 to three minutes. The course of things was different when the first inspiration was caused by pure want of oxygen, or when children were born by the Cæsarian section. In the case of healthy children, a minute might elapse before they began to breathe. The first inspiration was shallow, then followed a deeper, then a still deeper, and it was only after several inspirations that expiration with a cry followed. He believed it was the release of the compressed thorax, in the act of birth, acting like the relaxed pressure in the Marshall-Hall method that accelerated the first deep inspiration and first expiration with the cry.

Austria.

[From our own correspondent.]

Vienna, Feb. 9th.

Death of Professor Billroth.

The event of the week, one that by sheer force of character and genius of the deceased, has roused the sorrowful enthusiasm of the profession and populace of Vienna, has undoubtedly been the death of Professor Billroth, the affection for whom can scarcely be explained otherwise than by his exalted greatness. He was not an Austrian by birth or education, yet Vienna has this week mourned over him as for a hero, and has given him a public funeral, such as was probably never accorded to a private individual, and has laid his remains in a spot reserved for "the distinguished dead."

Deceased was born in 1829 in the island of Rügen, and was consequently but 64 years of age. He was the son of a Protestant pastor, and possessing a decided talent for music, he thought for a time of devoting his life to it, but in 1848 he went to Greifswalde, and later to Berlin and Göttingen to study medicine. At thirty he was Professor of Surgery in the University of Zurich, where he became an intimate friend of the renowned composer Wagner. In 1865 Billroth was invited to become the Director of the famous surgical school of Vienna, in succession to Professor Schur; this appointment he accepted, and for twenty-nine years he has not been absent from Vienna except for occasional holidays.

Although his genius as a surgeon was appreciated by the profession in Austria, his name was comparatively unknown to the general public until the outbreak of the Franco-German War in 1870-71, when he voluntarily placed himself at the service of Germany, and his name became a household word throughout the civilised world for the initiation of operations hitherto unattempted and for the daring and success of his surgery throughout that terrible conflict. But a feature in these brilliant exploits must not be overlooked, as they were undoubtedly in field surgery up to this time. I refer to the nursing and after-treatment of the wounded. Billroth was a man of Herculean strength and energy, devoting little time to sleep; he drilled his nurses male and female so continuously, practically instructing them by his own personal attention to the wounded, that they became effective in an incredibly short space of time and shared in his enthusiasm. The century has produced no greater surgeon than Billroth, and his name will be handed down to posterity as a man of original conception, brilliant powers, and noble character. Columns might easily be filled descriptive of his literary and surgical achievements—the extraordinary fascination he exercised over the profession and students with whom he came in contact. Suffice it, at least for the moment, to add that Austria was not slow to appreciate his greatness during life, and in death, as evidenced today, respect for his memory and grief at his decease were unmistakable. Royalty attended the funeral, the *élite* of Society filled the Protestant church, the profession and representatives of public bodies followed his remains in thousands, public buildings were closed, and Vienna mourned for the honoured dead. *Requiescat in pace.*

Laryngo-scleroma.

A case before the "Aertze" of a young Hungarian, æt. 24, who enjoyed good health till 1879, when a funnel-shaped contraction was observed in the larynx, which was diagnosed as chorditis vocalis infer. hypertrophica. At the recent examination the fundibular character had disappeared, but a thick membrane could be seen on intonation; on the right side a few pea-form bodies were removed which on being examined were found to contain a large quantity of scleroma bacilli. This confirms the opinion recently expressed by Professor Paltauf that most of those cases diagnosed as chorditis vocalis infer. hypertrophica may be classed as laryngo-scleroma.

Fungoid Keratitis.

Prof. Fuchs showed a miller by trade with a serpiginous ulcer on the cornea which on closer examination was found to be a covering of finely broken crumbs of bread, but when microscopically examined were found to be colonies of a fungoid growth. These have been cultivated and found to repeat themselves. He related two similar cases, which are all he can find in literature, where one had been originated with actual contact with the mouldy material of a pear accidentally thrown against it, whereupon the part struck became necrosed, the fungus daily increasing.

Prof. Mauthner related that his case was a girl, æt. 14, who, out walking one day, was struck on the eye with a leaf of a tree, which soon developed severe keratitis, which soon involved the whole structure in a peculiar manner.

Subclavian Aneurysm.

Ewald showed a case of aneurysm of the subclavian where the artery was tied and the sac opened. Pulsation at the radius was lost, but the ulnar pulse was present.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Tumour of the Brain.—Mr. Rose operated on a man, æt. 56, who had been admitted to the hospital some five weeks previously under the care of Dr. Ferrier. The patient's symptoms began six months ago when he had a series of fits, these were followed by transient right hemiplegia with aphasia, after which he was noticed to be more or less demented. The prominent symptoms on admission were more or less aphasia, double optic neuritis, hemianopia on looking to the right, and headaches; there was local tension over the left parietal region and some loss of power in the muscles of the cheek on the right side, and shortly afterwards he developed slight loss of power in the muscles of the right arm. There were no very definite local symptoms with the exception of slight tenderness and slight bulging over the lower part of the left parietal bone. There was word deafness and word blindness, but he had never had any vomiting. The patient since admission had gradually got into a state of more or less dementia. Fæces and urine were passed unconsciously. The scalp having been shaved and purified, the lesion having previously been localised by Dr. Ferrier, Mr. Rose marked the centre of the tender area by puncturing the bones through the scalp with a small electric drill, and then reflected the scalp from above downwards by an elliptic incision so as to thoroughly expose the parietal eminence; all bleeding points having been secured, the skull was partially cut through with an electric saw, a small trephine was next employed and the bone finally removed with chisel and bone forceps. The dura mater was found to be very tense and non-pulsating, and on incising it to the full extent of the external wound, a fungating tumour and a little purulent fluid appeared, pulsation being now detected. A small part of the tumour was removed for examination, total removal being impossible. Considerable hæmorrhage occurred, but it was arrested by ligatures and pressure. The skin was drawn together over the wound and a drainage tube inserted. Mr. Rose drew attention during the progress of the operation to the tense unyielding nature of the dura mater, and the absence of all intercranial pulsation until the membranes had been incised and the tension relieved by the escape of fluid and broken down tumour substance. He also remarked on the satisfactory localisation of the tumour which was found to be situated immediately under the spot indicated by Dr. Ferrier. He regretted that it was impossible to remove the mass, but owing to the absence of any capsule and to the soft nature of the growth, and its close incorporation with the brain substance, he considered it inadvisable to do more than remove a few fragments for microscopic examination, and insert a drainage tube for a time. The operation, he thought, would not be valueless to the patient, inasmuch that it relieved intercranial pressure and allowed room for expansion and growth of the tumour, so that, even if the disease were ultimately fatal, as was to be expected, the patient's life would be somewhat prolonged, and his condition distinctly ameliorated, at any rate for a time. Mr. Rose mentioned a similar case on which he had operated some years back in which, although the tumour could not be removed, the patient lived in tolerable comfort for six months, during which period there was a protrusion of pulsating brain substance of some size through the trephine opening under the scalp. In such cases he considered the trephine opening constituted a "safety valve" against excessive instrumental pressure. Microscopic examination showed the tumour to be of a sarcomatous nature.

It is satisfactory to note that since the operation the patient's condition has considerably improved.

ST. THOMAS'S HOSPITAL.

Carcinoma of the Scrotum.—Extensive Dissection of the Scrotum and of the Groin.—Removal of half the Scrotum and of all the Glands, Fasciæ, &c., in the Groin and Upper Part of the Thigh.—Mr. Anderson operated on a man, æt. 39, who, fifteen months ago, had noticed a slight hardness and swelling of the right testicle. This had come on without any appreciable cause; it increased gradually and the patient suffered a good deal of pain, especially after exertion. More than six months ago the testicle was excised in a provincial hospital. Since then two more operations had been undertaken for recurrences, the last one about two months ago before the man went to St. Thomas's. At the time of admission there was a fungating mass over the right side of the scrotum with hard everted edges, in the centre there was a sanguineous mass of tissue partly broken down. The discharge was very offensive; there was but little tenderness. The growth was limited to the right side of the scrotum, and the urethra was unaffected. The glands in the groin on the same side were indurated. Mr. Anderson deeply dissected away the whole mass of the right side of the scrotum and also the whole mass of glands in the groin together with the fasciæ over the muscles, getting right down on to the femoral artery; having to divide the internal saphenous vein, he left about half an inch of that vessel so as not to interfere with the femoral vein; he carefully dissected off with knife and scissors any suspicious pieces of tissue from the wound in the groin and also of the dartos till all parts of the wound appeared perfeotly healthy. The hæmorrhage was comparatively trifling, as the knife and scissors of the operator were carefully followed by Mr. Stabb, who at once secured any bleeding vessels. The stump of the cord left by the former castration was traced some distance up and cut off near the internal ring, where to all appearances it was not infiltrated. The remains of the fascia over the sartorius together with some muscular tissue was attached to Poupart's ligament by a few stitches, and the fascia on the inner side of the wound over the pectineus dissected up a little way and attached in a similar manner to the inner part of Poupart's ligament. The operator was enabled to bring the parts together so as to completely cover in both the groin and the scrotal wound, the cut edges of the dartos being sutured to the inner side of the skin wound and to the divided skin of the penis, thus making a convenient scrotum for the remaining testicle. Mr. Anderson remarked that the operation had succeeded far better than he had expected, as it was one in which the surgeon would look for great hæmorrhage and some difficulty in bringing together the edges of the wound, for it was absolutely necessary to remove all the disease; however, with care, there had been comparatively little bleeding, and he had been enabled to extirpate the whole of the disease and close the wound accurately; this last, he said, would probably be healed in a fortnight; but the great thing now was to watch for any recurrence at any part of the joining, and if it happened, to excise the affected portion at once. He pointed out that he did not remove the other testicle, though it might perhaps have been better to do so, but, viewing the age of the patient, he thought he would not be justified in absolutely depriving him of all procreative power. He commented also on the rarity of carcinoma in this situation, the growth he had removed had been proved to be carcinomatous and not epitheliomatous by microscopical examination of a portion before operation.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 14, 1894.

MODERN SANITARY VIEWS.

The speakers at the recent Annual Dinner of the Sanitary Inspectors Association presented their hearers with what may be regarded as a kind of bird's-eye view of current sanitary topics. Canon Leigh, for example, emphasised an opinion that is fast gaining ground when he claimed that the clergy should take an active interest in all matters affecting the physical as well as the spiritual well-being of the people. His contention that the National Church should lead the way in sanitary reforms expresses the tenets of a new school of priests, at once earnest and progressive, who recognise that the conduct of human life cannot be left entirely to religious precept and dogma. Another speaker, Sir Thomas Crawford, reminded his hearers that long before sanitation became a matter of general interest it was a subject constantly studied by the medical officers of the public services. Nor can it be doubted that many valuable facts have been recorded by the pioneers in question, who have had in many cases exceptionally good opportunities of studying the conditions and surroundings of various types of epidemic disease. Indeed, one could not imagine more suggestive reading than the continuous reports of a large body of technically-trained men, who, from the nature of their occupation, are brought into contact with all the varying conditions of climate, race, and soil met with in the shifting kaleidoscope of life in camp and in barrack. The utterances of the two members who responded for the Houses of Parliament were both noteworthy. One of them dealt with the Parish Council Bill, which he fervently hoped might become law, so that they might be able to set up in each parish the means of getting out of those insanitary conditions which were at once a perplexity and a disgrace. This language, although strong, is more than justified by the apathy, the ignorance, and the hopeless *laisser-faire* which characterise sanitary administration in rural districts. The second member, Mr. Pickersgill, referred to the unhealthy state of the House of Commons itself, which he wittily described as a kind of Alsatia so far as escape from sanitary inspectors was concerned. Notwithstanding this curious anomaly, he justly claimed that the House of Commons was thoroughly alive to the question of sanitation. He regarded the Public Health (London) Act of 1891 as an excellent piece of legislation. "It was useless, however, to have these measures unless they were properly administered, and the number of sanitary inspectors in most London districts was disgracefully inadequate. It was precisely in those districts where the closest inspection was required that the number of inspectors was lowest. In Bethnal Green, for instance, there were at most four inspectors, who could not possibly make the house-to-house visitation required by the Act." In calling public attention to this matter, Mr. Pickersgill has placed his finger on the most glaring defect of modern administration, not only in the metropolis, but throughout the length and breadth of the Kingdom. Before the law can be at all efficiently carried out, it is absolutely necessary that medical officers of health should have the services of an adequate number of well-paid and thoroughly-trained sanitary inspectors. The same speaker touched on the question of cost, and made the sensible suggestion that, as sanitation was a matter in connection with which the interests of all parts of London were identical, the expenses of inspection should be borne by a common fund. Some such arrangement will plainly be needed if any general scheme of sanitary reform is to be carried out in the Metropolis. The poorer parishes are already saddled with an enormously high rate, which is relatively far larger than in the richer districts. Indeed, it is not unreasonable to assert that centralisation must be a necessary preliminary to comprehensive sanitary administration. Among the remaining speakers, Mr. Diggle made rather a lame defence of the School Board. He claimed that if some of the schools had been found to be insanitary it was the fault of those whose education had in the past been imperfect, and who had constructed the drains improperly. Surely the principles of drainage were fairly well understood before the advent of Board schools. We fancy if Mr. Diggle saddled the right horse he would blame the loose contracts entered into by the Board and the neglect of proper supervision as to their fulfilment. On the whole this was an interesting occasion, and the speeches appear to have been far above the ordinary after-dinner average. Sanitary inspectors, as a class, are a deserving body of men: their duties are arduous, and their pay and chances of promotion alike poor and precarious. Yet it is by them, as pointed out by the President, that the task of making this country as cleanly as it could be, and a garden altogether, can alone be accomplished.

◆

THE DERMATOLOGICAL SOCIETY QUESTION.

The attention attracted by our articles on the subject of Dermatology in London, and the publication of Mr. Hutchinson's letter in our last issue, demand some further observations from us in connection therewith. As a preface of what we have to say upon this occasion we may remark that it has come to our knowledge that the articles in question have been generally attributed to a well-known London dermatologist by whom the suggestion of the formation of a new Dermatological society was first mooted. This assumption is absolutely without foundation. At the public meeting held at Mr. Hutchinson's Clinical Museum some weeks ago the facts in connection with the case at once became common property, and the individual opinions which were then expressed in favour of the new society emphatically indicated that a society devoted to dermatology, based upon broad and comprehensive lines, was certainly required. For the time being we deemed it best not to comment upon the matter, preferring to watch the development of the scheme, without drawing public attention to the under-current of ill-advised opposition to its inception, the presence of which certain speakers at the meeting had been so successful in demonstrating. However, further facts in connection with this opposition leaked out, and, in the natural course of things, came under our notice, as the result of which we deemed it our duty to comment fully upon the subject, not, let it be clearly understood, with the object of favouring one side more than the other, but solely for the purpose of throwing some light upon the state of affairs of which so many dermatologists throughout the country, in regard to their speciality, have had recently so much reason to complain. If, in the remarks which we felt bound to make, we have offended certain estimable members of the speciality, we cannot be held blamable, and the curious point is that, although Mr. Hutchinson "regrets very much" that we should have drawn public attention to the matter, his letter, published in our last issue, emphatically confirms every remark that we have made. Evidence more convincing could not have been produced of the rectitude of the strictures to which we have given expression; moreover, there are points in his letter which introduce new features to which further exception may be taken. He sententiously remarks that "there are some of the members of the old society who regard with suspicion the formation of a new one" (!) Why this suspicion? Again, "I feel sure," he says, "that your criticisms are calculated not to diminish but to increase the state of tension which already exists." Why this state of tension? What reasons exist by which it should ever have developed? Are not the advocates of the new society, led by Mr. Hutchinson himself, some of the best known dermatologists in the kingdom? And has not their cohesion to the scheme been sufficient to show that it was worthy of the support of all dermatologists? Clearly, after the pronounced and general opinion expressed in favour of the organisation of a "Dermatological Society of the United Kingdom" the old Society should have placed itself at the head of the movement, and taken the initiative in bringing it to a successful issue. But no, the old Society has intimated its intention of preserving its autonomy intact, and of taking up the position of what we may describe as the "Royal Society of Dermatology," to the charmed circle of which only those who have "graduated" in the new Society will have any chance of admission. "As vacancies occur," says Mr. Hutchinson, "in the ranks of the thirty, it [the new Society] will hope to supply worthy candidates who have been trained in its ranks." Can any dispassionate person believe that there is any necessity for two societies of the kind, more especially when the intention seems to be to draw an invidious distinction between them? We are compelled to conclude that there must be interested motives which have prompted the opposition in this matter, and we feel it our duty to state that this opposition is unbecoming on the part of gentlemen of the professional status of those who are responsible for the present unfortunate dilemma.

◆

LEAD-POISONING.

Now that general attention has been so pointedly drawn to the evil effects of lead upon workers in that metal the public newspapers are naturally full of the subject. Leaders, leaderettes, paragraphs, reports of inquests, and other items of lead literature are poured forth in profusion from the daily press. Indeed, if we mistake not, the late Commission of Inquiry into the whole subject of lead-poisoning in manufactures was the outcome of one of the better phases of the "new" journalism which has agitated so long and so persistently for the investigation and the reform of the conditions surrounding the "dangerous trades." The departmental commissioners on this particular board were well-chosen and representative, being composed of Mr. Gould, Superintending Inspector of Factories; Dr. Oliver, of Newcastle-on-Tyne, an expert; Professor Dupré, Lecturer on Chemistry at the Westminster Hospital School, together with an Inspector of Factories and an Assistant Secretary of Mr. Asquith's. Their object was to inquire into the facts and surroundings of the various lead manufactories and industries. The magnitude of their undertaking may be gathered from the statement that the Commissioners in the course of their labours visited no less than forty-six works in Great Britain, and examined one hundred and eighty-four witnesses. Upon the mass of evidence thus collected they have founded a report which, unlike most documents of the kind, is remarkable for its clearness and conciseness rather than for its length. The various symptoms of plumbism, both acute and chronic, are minutely described, but there is no need in the columns of a medical paper to do more than make a passing mention of this part of the report. Suffice it to say that the baneful and insidious nature of the poison no less than the minuteness of the amount required to produce its evil effects upon the human system are fully insisted upon by modern medical authorities. As to the channels of entry of the poison into the system, the Committee formulate the following conclusions:—"(*a*) That carbonate of lead may be absorbed through the pores of the skin, and that the chance of this is much increased during perspiration, and where there is any friction between the skin and the clothing; (*b*) That minute portions of lead are carried by the hands, under and round the nails, &c., on to the food, and so into the stomach; (*c*) But that the most usual manner is by the inhalation of the lead dust. Some of this becomes dissolved in the alkaline secretions of the mouth, and is swallowed with the saliva, thus finding its way to the stomach. Other particles of dust are carried to the lungs, where they are rendered soluble and absorbed by the blood." This passage affords a good example of the clear and concise nature of the report, to the original of which all who are interested in the subject may be referred. The Commission has thrown much light into tangled byways, for the prevention of plumbism may be regarded as one of the most Protean of nineteenth century problems. Quite recently another aspect of the question was brought forward at an inquest held upon the body of a woman who died of lead-poisoning. The doctor who had attended deceased advised that all such cases should be notified. At present persons thus affected avoided the medical officer of the works, as he would stop further employment until patients were cured. The view thus advanced by the medical man, strange to say, was taken up warmly by the jury, who appended to their verdict the following rider:—"The Jury desire the Coroner to suggest to Her Majesty's Government that provision should be made compelling all medical men to report all cases of lead-poisoning to some central or local authority, to prevent those suffering from lead-poisoning avoiding examination by the medical officer of the works before continuing their occupation." This is, indeed, an advanced standpoint, and may be taken as a proof of the rapidity with which public attention may be caught and trained through the medium of the press. Nor can reform be far distant now that the national conscience has been awakened to the numerous unhealthy and noisome trades that are carried on in their midst. The Government Commissions have proved beyond the shadow of a doubt that Capital has to answer for an enormous waste of life by its neglect of ordinary precautions that may at least lessen the avoidable risks. Dangerous trades there must always be, but there are few in which, properly and scientifically guarded, the injury to life and health may not be considerably curtailed. It is with peculiar pleasure, then, that all who are interested in the welfare of the labouring community will welcome the valuable reform which is being introduced by the present Ministry. The doctrine of State interference with Capital in order to ensure the safety of workmen may be regarded, under certain limitations, as one of the soundest natural laws by which the future course of social progress will be guided and governed.

◆

Notes on Current Topics.

The Death of a Medical Man from Tetanus.

We would have wished that the medical history of the case of a medical man who died at Hull last week from tetanus had been more complete, for the newspaper reports which have reached us leave a good deal to be desired in this respect. The case, nevertheless, so far as it goes, is altogether of an unusual type. The deceased, who was in the active practice of his profession, was thirty-six years of age, and for about a week before his death complained of some swelling and pain in one foot and leg. Little attention seems to have been paid to this, and no evidence was forthcoming to show to what cause the swelling was attributed. On the morning, however, of the day when death occurred, a neighbouring practitioner was summoned, and found the deceased suffering "from lockjaw in a marked degree." The evidence of this witness may here be quoted. "I asked him (the deceased) to put out his tongue, but the exertion brought on the spasm, and he bit his tongue. I then inquired for other symptoms, and found the spasm had commenced in his lower extremities. He was then able to talk, and was quite rational. I remained with him an hour and promised to return in the evening. I received an urgent message in the evening to go and see him, and then found him at the point of death. I noticed a spasm cross his mouth, and he expired almost immediately after I arrived. I afterwards made a post-mortem examination, as far as it was necessary. I found a great many small wounds in the lower extremities, and on other parts of the body, the signs of other wounds which had healed up. I understand that two needles had been found embedded in the flesh by the women who laid the deceased out. They were needles used to administer medicine, which was no uncommon way." Such is the newspaper report, and further inquiry from the witness elicited the fact that cocaine was the drug the hypodermic injection of which had been resorted to. Under the circumstances, however, we think that a full and complete post-mortem examination by two medical men should have been carried out. If a post-mortem is deemed necessary at all, in every case it should be fully performed, for the purpose of avoiding any possibility of error. The connection between the development of tetanus and the wounds of the hypodermic needles does not by any means appear to be plain from the evidence adduced in this case.

Discharged Lunatics and Crime.

From time to time the British public is startled by some tale of criminal atrocity committed by a discharged lunatic. Quite lately there was such an occurrence at Fulham, where a man who had shortly before been released from an asylum murdered his child in a most cold-blooded manner. There can be no doubt that this man was still insane when allowed to leave his restraint for the outside world. It is notoriously hard to decide whether a man is suffering from homicidal mania, and behaviour of such an one is of course considerably influenced while under the discipline of an asylum. In a case of this kind, however, one would expect the responsible medical officers to exercise very great caution before turning loose upon society so dangerous a lunatic, more especially if he had at any previous time shown any symptoms of actual homicidal tendency. Unfortunately, nowadays there is a great danger of confusing a lucid interval or intermission in cases of lunacy as a "cure." That superintendent is regarded as the most successful who can point to the greatest percentage of these so-called "cures." It would be interesting to obtain statistics, if that were possible, as to the amount of crime directly committed by persons released from lunatic asylums. These figures could not fail to be of interest if compared with the discharges and readmissions taking place under each individual superintendent. The importance to the public of the proper detention of homicidal maniacs is so obvious as to need no more than a passing mention.

The Chelsea Hospital for Women.

The Medical Officer of Health for Chelsea has just laid some serious indictments against the Chelsea Hospital for Women. In the first place, with regard to the operative surgery of the institution, out of 650 patients admitted to the hospital last year, there were 36 deaths, but of these, 21 resulted after surgical interference. This serves as the text of a lecture to the medical staff, who are reminded that, as many of the surgical diseases peculiar to women are not dangerous to life, operative measures should not be undertaken unless the prospects of a cure as a result thereof are almost assured. The inference, therefore, is that, of these 21 patients who died, some or many might yet be living had no surgical interference been attempted. But another serious matter is that the drainage and sanitary arrangements of the Hospital are so defective that it is absolutely essential that the institution should be closed until the Governors have carried out the necessary alterations. The Chelsea Vestry, under whose notice these indictments have been brought, have been so impressed with them that they have unanimously resolved to report the whole matter to the Local Government Board and to the Home Secretary, with the view of an inquiry being held into the past management of the institution. But whatever the facts of this case may be, we doubt the expediency of a medical officer of health lecturing a hospital staff reflecting upon the treatment which the latter seem fit to adopt in regard to their patients.

Medical Men and the Police in Liverpool.

The Liverpool Stipendiary has received a letter from the authorities of the Liverpool dispensaries to the effect that the following resolution had been passed with reference to the diagreement which lately arose from the refusal of the medical officers to give certificates to the police in the case of accidents: "The medical officers are hereby instructed that in all cases treated at the dispensaries they shall, whenever asked to do so by the police, give a written certificate decribing the nature of the injury sustained, and whether dangerous or otherwise." The effect of this resolution will be to remove all sources of friction in the matter, and there is no reason now why harmony should not prevail in the future between the police and the medical officers concerned. The decision which has been arrived at is entirely in accord with the opinions which we expressed when the subject was first discussed. Medical officers holding resident appointments as house surgeons at public institutions stand on a different footing in regard to fees claimable for giving evidence in comparison with private practitioners, and as long as the law remains as it is, there is no redress. To take only one instance, it is impossible to see the justice of house surgeons being excluded from claiming a fee for attending at a coroner's court in respect to an inquiry into the death of a patient at a hospital. We cannot admit any just grounds why this exclusion should have been made. Morally house surgeons are fully entitled to a fee for giving evidence before a coroner, and the law should certainly be amended in this particular.

A Way Out of the Baking-Powder Difficulty.

The failure of the authorities to secure the conviction of a man who sold baking powder containing alum, to which we referred in a recent issue, has attracted general notice. As was pointed out at the time, the prosecution fell through by reason of the judges taking the view that under the clauses of the Adulteration Act baking powder could not be regarded as a food. In order, however, to render themselves independent of the manufacturer's supply of this commodity, the suggestion has been made that housekeepers would do well to make their own baking powder. The formula recommended is as follows:—Tartaric acid, one part; bicarbonate of soda, two parts; and corn-flour, three parts—the ingredients to be well mixed, and then passed through a fine sieve. Doubtless where housekeepers are concerned in using baking powder this home-made commodity would be highly serviceable, but in the case of the public, which has to rely on the products of shopkeepers, the suggestion would not prove of much value, unless the shopkeepers found that their supplies of baking powder could be more cheaply produced at home by this formula than by the manufacturers.

Dr. John Fox, of Greenock, whose death occurred a few days since, became a Licentiate in Medicine exactly 60 years ago. He was the oldest practitioner in the district, and was much esteemed.

The Dentists' Register.

The official record of dentists was issued last week, and it supplies material for thought, especially for those who practise that speciality, and who look forward to raising its professional level. The first fact which strikes us is that there does not appear to be in dentistry that tendency to overcrowding which the medico-chirurgical profession suffers from. But one dentist has been added to the speciality in the course of the year. This, however, does not mean that there are no candidates for dentistry, but that the hairdressers, tobacconists, and other hangers-on of dentistry, who got themselves registered in 1878 on a diploma granted by themselves to themselves, are, as they die off, being steadily replaced by educated practitioners. The dental profession will, however, have to wait a long time for the expurgation of the Register by this means. The period of sixteen years which has elapsed since the Dentists' Act passed has served to reduce the ranks of the uneducated to 72·35 of the percentage of the aggregate, and to increase the ranks of the educated to 26·48 of the entire profession. If the expurgation proceeded no quicker than this, it would require an age to complete the process, but, of course, the educated dentists may trust the influence of increasing old age to clear the ground of a rapidly increasing number of these interlopers.

We observe that the degrees of D.M.D. Harvard and Michigan, which were admitted to registration a few years since by the General Medical Council, are no longer recognised in this country, respecting which we shall have something to say later on. Mr. Miller, the energetic and intelligent Registrar, has taken great care in the correction of this Register, so that every dependence can be placed on the statistics which it contains.

Spurious Sausages and the Public.

The public sometimes is roused to show its dissent at the impositions practised upon it by enterprising tradesmen who lightly disregard the risks of prosecution under the Food and Drugs Adulteration Act, and a Holloway confectioner, for offending in this respect, has found it necessary to have his shop guarded by six constables. In the course of a trial it transpired that this same confectioner dealt in sausage rolls. Now sausage rolls are oftentimes more "fearfully and wonderfully made" even than the sausages themselves, and no person should think of indulging in one of these articles, at say the bar of a railway refreshment room, without having performed a preliminary operation requisite to expose the condition of the contents. It goes without saying that the interior of a "roll" has none of the characteristics of a sterilised chamber; consequently, from a scientific point of view, the fungi which are found to grow so luxuriantly there would not be of the nature of pure cultivations! But this is merely one aspect of the natural history of a sausage roll. The offence of which the confectioner was guilty, and which led to his requiring police protection, was that his sausage rolls contained no sausages at all, but merely bread tinted with red ochre, for the purpose of giving a colour "like beef" to the contents. This is a new phase in the manufacture of these commodities, and it is satisfactory to know that popular opinion is against the astute tradesman who has attempted to push such spurious articles upon his customers.

"Covering" of Unqualified Dentists.

The British Dental Association has been successful in obtaining a legal judgment which will help them to put down illicit practice. A person named Duff practised in Plymouth as a dentist in a house labelled "Dental Surgery," his cards bearing the same legend with his name. He had been registered, but, from some unexplained reason, is not so now. The defence was that Duff did not pretend to be anything but the assistant of a dentist named Passmore, who lives in Exeter, and who would be entitled to use all the distinctive appellations used by Duff. The Court held that there was nothing to show the public that the Plymouth business was worked by anyone save Duff, and it accordingly convicted and fined him for using professional titles. Passmore, the "coverer," has not yet been proceeded against, but will, we expect, be dealt with before long.

The Value of an Eye.

In damages for personal injury the loss of an eye usually commands a high price. This was certainly the case a short while since at Bolton, where Judge Jones awarded £1000 to a soda-water bottler, whose eye had been destroyed by the bursting of a bottle of soda-water. From the evidence it appeared that the plaintiff was not wearing a face-guard, and that his employers had failed to provide any such protection. The accident, so it was claimed, could not have happened if the firm in question had furnished the necessary guards. One is glad to see that under these circumstances the judge insisted on the liability of the employer. Nor does his assessment of damages appear excessive, when we take into consideration how seriously the loss of an eye must injure the future prospects of a workman, to say nothing of the risks of sympathetic mischief in the remaining eye.

An English Ophthalmic Surgeon for the Shah of Persia.

Some few years ago the consort of the Shah of Persia visited Europe for the purpose of having an iridectomy performed for glaucoma. But before the visit was undertaken the Shah took counsel with his medical advisers as to whether the operation could be safely performed. With the alternative of losing their heads in the event of a catastrophe happening, they sanctioned the proposed step, and, fortunately for them, everything came right in the end. Now we hear that a young English ophthalmic surgeon has just agreed to journey to Teheran for the purpose of attending to the eyes of the Shah's eldest son.

The Public Analysts' Society of Great Britain and Ireland has re-elected Sir Charles Cameron, Superintendent Medical Officer of Health for Dublin, to the Presidency of the Societ

Leprosy and Vaccination.

Under the above heading a certain Mr. Moxley, who dates from King's College, Cambridge, has written a letter to the *Echo* (Feb. 1, 1894), which, as is usually the case with anti-vaccinationist communications to such journals, is brimful of misleading statements and fallacious conclusions. The writer's theme is a paragraph in Dr. Thin's article on the Indian Leprosy Commissioners' Report in the *Fortnightly Review* last month, and, of course, he has cleverly seized upon anything which might influence the popular mind against the practice of vaccination. It so happens that, in the opinion of many authorities who have closely studied leprosy, Dr. Thin has himself taken a rather exaggerated view as to the danger of infection from leprous sores, and his contention that slight abrasions of the skin of healthy persons offer a ready means of entrance from the moist sores of the leper, is, to say the least, as much open to question as that the sores on the leper's body are densely covered with free bacilli. In point of fact, the latter are not found in the sores of the large class of so-called "anæsthetic" cases. It must not be forgotten, too, that it has been abundantly proved, clinically and experimentally, that leprosy is one of the most difficult of diseases to inoculate—indeed, the only instance of a successful human inoculation on record is that of the Hawaiian convict Keanu by Dr. Arning; and even in this case it is doubtful whether the man had not already the disease in his system. Mr. Moxley's statement that vaccination in the Sandwich Islands and the West Indies is indiscriminate is, to put it mildly, not correct—the fact being that for many years past, nothing but bovine, or imported lymph has been used by the Hawaiian and most of the West Indian authorities. It is probably useless to appeal to facts where anti-vaccinationists are concerned; but those interested in the question will find it fully discussed in the Report of the Vaccination Committee, Part iii., in Dr. Abraham's papers in the "Proceedings of the International Congress of Hygiene, &c.," 1892, and *Journal of State Medicine*," April, 1893, as well as by Drs. Rake and Buckmaster in the Indian Leprosy Report.

The Dublin Hospital Sunday Fund.

The annual meeting of the supporters of the Fund was held last week, and the proceedings were of the usual routine character, save that a debate took place with reference to a recommendation of the Visitors that the Orthopædic Hospital should be merged in one or other of the large general hospitals, a proposition which was strenuously objected to by the representative of that hospital. He pointed out, with great force, that, if there is any form of disease in which a special hospital is required, it is in the malformations to which this hospital is devoted. Everyone knows that these cases are excessively tedious, and must be kept in hospital frequently for months together, during which the treatment is, to a great extent, by special mechanical appliances. No Dublin hospital has bed accommodation for such never-ending cases, nor money to spend on keeping an individual patient for so long a period, nor nursing facilities for looking after a crowd of children who are quite healthy except for the deformity. The conditions are, in fact, not within the means of a general hospital, and must necessarily be met by a special institution which will, probably, be largely supported by the parents of children, and only partially by voluntary contributions. The method by which the Reports of Visitors are presented to the Hospital Sunday meeting has led to a good deal of bickering from year to year. Two Visitors are detailed by the Distribution Committee to visit an hospital, and, after inspection, they make a written report setting forth deficiencies, if any, in the institution visited and suggestions for remedy. We say that these reports are good honest reports. They do not attempt to please everybody, and they generally hit the blots fairly and expose them with commendable candour. The opinions expressed are, however, only the opinions of two estimable gentlemen, and cannot be expected to be always free from fads, or be evenly just to the hospital administration. The complaint is that the criticisms of the Visitors are kept carefully secret, even from the members of the Council of the Fund, until the day when they are presented for approval, and it is avowed that this is done lest the representatives of the hospital might attend and dispute the adverse verdict passed upon their hospital by the Visitors. This being so, it is evident that the reports must be taken as purely *ex parte* and personal, yet they are put forward to the supporters of the Fund as the expression of the opinion, not only of the Visitors—not only of the Committee of Distribution, who are favoured with a private view of them—but of the Council at large, who have never seen them at all until they are put into their hands three minutes beforehand. We have already protested against this system. The reports should either go forth to the public as the *ex parte* opinion of two gentlemen, perhaps confirmed by the Distribution Committee, or else the Council should be afforded an opportunity of hearing both sides and finding a deliberate verdict on the evidence.

More Notification Liabilities.

We have it now, on the authority of the Editor of the *British Medical Journal* (whom we may truthfully designate the great Notification evangelist), that if a medical practitioner notifies a case as infective, and it is removed to hospital as such, and that the diagnosis turns out to be erroneous, a claim for compensation may be legally sustained by the patient's friends against the notifying doctor, and that "it would be desirable to come to some arrangement with the parties if a reasonable sum representing the actual loss of time and expense were named." This is, we think, good law, as most of the pronouncements of the same authority are, but it opens up a pleasant vista of contemplation for the practitioner. It may be questioned whether the much-coveted half-crown fees now earned by notification will cover the "reasonable sum" for compensation to be paid by every practitioner who makes a mistaken diagnosis, not to speak of the incidental law costs.

Paying for Leave to Work for Nothing.

The re-organised Galway County Hospital does not appear to be in a much better financial condition than the old County Infirmary which it supplanted, and which was brought to bankruptcy by the politico-sectarian feuds of the Board of Governors. At the last meeting of the Board a claim for £26 was made against the medical officers for what were called "guarantees." On elucidation it appeared that this sum represented the maintenance of patients recommended by the medical officers, and that these gentlemen, while willing to pay for accident cases, as they undertook to do, were not disposed to pay for the keep of every sick man they recommended, in addition to giving their work and time for nothing. This seems to be a strange state of things. If the County Hospital cannot be kept open legitimately by the contributions of the benevolent and by other sources of income, it must have very little hold on the county, and must realise in a very slight degree the anticipations of those who destroyed the Infirmary in order to build the Hospital on its ruins.

Death under Anæsthesia.

A fatality under anesthesia occurred in the Adelaide Hospital, Dublin, on the 8th inst. The patient was a young and apparently healthy man from whose leg it was necessary to remove diseased bone. The examination of his heart disclosed no abnormal condition, except that the action was tumultuous. A few drops of chloroform were first given, which checked the palpitation, but as the heart seemed to fail ether was at once turned on. There was, however, no rally, and in spite of every effort he died from syncope in twenty minutes. It was stated in evidence that this is the first fatality under anesthesia which has occurred in the hospital since 1879.

The Contagious Diseases Act.

It appears there is still a hope among the English army authorities that the Contagious Diseases Act may one day be reimposed. The attention of the Commander-in-Chief has been drawn to the moral condition of certain seaport and garrison towns. After careful consideration he has addressed a circular letter to generals commanding districts. He refers to the advantages conferred on a district by the Act quoted. In the abeyance of that measure, however, he asks the local authorities to exercise the powers vested in them by the Criminal Law Amendment Act, 1885, and also by the Licensing Acts. He asks commanding officers to co-operate with magistrates in a serious effort, by determined police action, to free the towns from this disgrace. All this sounds very much like a confusion of ideas. The Contagious Diseases Act was aimed not so much against vice and immorality as against the propagation of a filthy and dangerous disease. Its beneficial action has been stayed by a small but influential band of sentimentalists. But this hardly concerns the morality of a district, except that the police have the power of detaining prostitutes who are known to be diseased. If the Duke hopes to reform the morals of the British soldier and of garrison towns by a rigorous police system, we fear that the end of his journey will be far distant. To educate the private soldier into some sort of self-respect and knowledge; to let him hope by promotion and by better pay to increase his facilities of marriage, would seem to be more hopeful proceedings. It may be doubted, however, when all is said and done, if the standard of morality would ever be very greatly raised when one has to deal with a large body of healthy, active men, for the most part young and unmarried, and resolved to live up to their traditional pleasures. Anyway, the police are not likely to work this wonder!

River Mud in Adulteration.

The Chinese have always distinguished themselves as a nation by the untiring ingenuity with which they tread the devious paths of fraud and deceit. One of their latest achievements in that direction has been exposed in America, where a New York Inspector found the kind of tea known as "shotty gunpowder" although palatable enough, to be partially composed of "exhausted and spurious leaves rolled into gunpowder pellets and given consistency and weight by a peculiar paste." We are further informed that the paste used for this adulteration is made from Sing Poo mud and rice water, coloured with gypsum, indigo and other substances. River mud has been utilised for a variety of purposes in the arts and manfactures, for instance the finest cement in the world is obtained from the Thames mud, but it has been left as a triumphant tribute to Celestial trickery to annex so disgusting a material to the purposes of food adulteration. When one realises the abominable filthiness which characterises most of the Chinese rivers, one can only hope that the day will soon be at hand when the whole of the tea supply may be drawn from other countries, where the Heathen are less trickily inclined. It is a wonder that the enormous falling off in the tea trade has not warned China that honesty is the best policy as regards her staple product.

The Electric Belt Trick Again!

A quack named McConville, who passes under the name of "Professor Hamilton" in Liverpool, has been sent for trial for swindling a patient out of £52 12s. by the electric belt dodge. The victim appears to have been a natural phenomenon, for he is described as an Irish labourer, and we can testify that one of that ilk with fifty guineas to spare for a quack is a veritable curiosity. An interesting piece of evidence given at the trial was that of an assistant, who stated that he made up the so-called medicines but that there was also in the establishment "a fully qualified medical practitioner who received 30s. to £2 per week, his principal duty being to answer the door."

An appointment as honorary physician to the Queen has become vacant by the death of Inspector-General R. Lawson, half-pay of the Army Medical Department, at the age of 79 years. The deceased officer entered the Army in 1835 and retired in 1872. He served in the Crimean campaign, for his services in which he received the medal and fourth class of the Medjidie.

Physicians their own Dispensers.

The intention of the Royal College of Physicians of Ireland to remove the prohibition against its Licentiates making up their own medicines has been carried into effect, and the last batch of such Licentiates were, we believe, sworn in without the clause of the declaration which prohibited their doing so. This is a very wise concession to the altered circumstances of medical practice, and it is gratifying to see that the College is commencing to look at such questions with the light of common sense, which, be it said with respect, it has, heretofore, not been accustomed to do. The privilege of dispensing medicines thus extended to Licentiates does not, as we have pointed out, cover the compounding of medicines for any but their own patients. The right of making up medicine for the general public in Ireland still rests with the Apothecaries' Hall and the Pharmaceutical Society.

The New Medical Officer of Health for Liverpool.

The new Medical Officer of Health for Liverpool, who was unanimously appointed by the Liverpool County Council last week, is Dr. E. W. Hope. Dr. Hope has for some time discharged the duties of Deputy Medical Officer, and his election therefore has given general satisfaction. The retiring allowance of Dr. W. Stopford Taylor has been fixed at £291 18s. 7d. per annum, in accordance with the Liverpool Corporation Act of 1893.

The Prosecution in the Harness case were given by the magistrate at Bow Street a week to decide whether after the defendants had been discharged they would proceed under the Vexatious Indictments Act. At the expiration, however, of the stipulated time no further action in the matter had been taken.

"Esophagotomy" and "akromegaly" are the latest innovations in the spelling line of our American contemporary hailing from "Filadelphia." Both are "beautiful"-looking words! In the same issue of the journal we notice "*Hypodermatically*"—which seems to have a decided hypertrophied appearance about it in the midst of so much orthographic atrophy.

The Birmingham Vaccination Case.

The case of the workhouse boy whose friends brought an action on his behalf against the Medical Officer of the Birmingham Guardians for assault arising out of the boy's compulsory re-vaccination, has been tried again in the local court, and has resulted in a verdict for the defendant, with costs. When the case was previously heard—some twelve months ago—the sitting judge held that the re-vaccination was justifiable in the interests of the institution. Thereupon the Divisional Court was appealed to, and the cause was remitted by that tribunal to Birmingham to re-try it on the issue whether the boy was a consenting party. This was, in fact, the only question, the boy, who is twelve years old, being in the care, at the period of the alleged assault, not of his parents but of the workhouse authorities. The jury decided that he had given such consent, but they added to their verdict a suggestion that in future it should be made more clear that a person has the option of being re-vaccinated. The anti-naccination party ought surely now to be satisfied with this last snub which they have received.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Morison Lectures on Insanity.—Dr. Batty Tuke delivered the second lecture of this course on Wednesday last week. He first described the lymphatic arrangements of the brain, contending that without a correct understanding of the system by which its drainage was carried on, no true conception of its pathology could be attained. He proceeded to discuss how the normal economy of the brain might become implicated by disease. From the point of view of the anatomist and physiologist, mental action was a function of connections. The grey matter of the brain was a field for the association of efferent sensory impulses, where they are placed in communication with efferent tracts, along which impulses travelled, either at once or subsequently, and justification existed for the inference that when the continuity of these connections was interrupted, modification of function must ensue. The most advanced views with regard to the anatomical relations of the areas only afforded an explanation of the physical conditions necessary, and did not attempt to explain the nature of psychical processes. Moral causes, however, were undoubtedly inducers of physical changes in the tissues, and psychical activity was accompanied by an increase of blood supply to the brain. In two cases which he had seen, and in which, as the result of accident, there were openings in the skull, the brain bulged during mental action and withdrew afterwards.

Rabies in Glasgow — Important Decision by the Health Committee.—The prompt and effective measures hitherto taken by the Health Committee to stamp out small-pox in the early stages of the late outbreak are now being repeated for the purpose of stamping out rabies, which there is good reason to believe has obtained a footing in the city. Dog madness has been prevalent in Renfrewshire, cases having been reported from Paisley, Coatbridge, and the districts round Glasgow, and as there is strong evidence that several dogs in the city had been infected, the Committee on Monday last resolved to act upon the recommendation of Dr. Russell, Chief Health Officer, of stamping out the malady, and the magistrates at their meeting on the 1st ult. have issued the muzzling order, which is to remain in force for three months. The sub-Committee of Health have decided to pay the expenses of persons bitten by mad dogs on being sent to the Pasteur Institute, and two men who were bitten by a dog suspected to have been suffering from rabies are now on their way to Paris under the charge of Dr. A. K. Chalmers Junior Health Officer. The same dog which bit these two men also bit a Mr. Currie, an architect, before it was caught and killed. Mr. Currie has gone to the Pasteur Institute at his own expense, and a Glasgow constable went to Paris a fortnight ago for treatment, as he had been also bitten by a rabid dog. Dr. Chalmers has taken the brain and spinal cord of the dog with him for the purpose of ascertaining whether the dog was or was not affected with rabies.

Damages against a Glasgow Practitioner.—Sheriff Guthrie has given damages in an action by a quay labourer against a Govan medical man for £16 16s. and expenses. In giving judgment his lordship said that on the 10th November defendant's assistant in his surgery supplied the plaintiff with carbolic acid instead of carbolic lotion, which, being applied to plaintiff's leg, burned it, whereby pursuer was disabled for some weeks, and was unable to follow his usual employment as a quay labourer. His lordship said it was the duty of medical men and druggists to take precautions against the stupidity, negligence, and defective memory of their customers. Such precautions had not been taken in the present case.

A New Infirmary for Paisley.—A special meeting of subscribers to the Paisley Infirmary was held on the 9th ult. for the purpose of considering the necessity of additional accommodation. The Chairman of the Infirmary Directors reviewed the various efforts which had been made towards the getting of a new infirmary. Their difficulty had been the want of money, but the bequest by the Barbour Trustees, which had been altogether unexpected, had now placed all financial difficulties out of the way. The sum given by the Trustees of the Bequest amounts to £15,000, free of legacy duty, the condition being that the Directors exhibit to the Trustees a satisfactory plan for a new infirmary on a new site to be approved of by the Trustees.

Glasgow University Jottings.—Last week an important matter was brought before the Grand Committee on Medicine for consideration. It was proposed to ask the Senate of the University to shorten the time occupied by the final examination in medicine. Under the present system the examination starts at the beginning of June and lasts for about six weeks. As there is no good reason why the examination should be prolonged to such an extent, it will be a great boon to all medicals if the proposed reform comes into force.

SOCIETY FOR THE STUDY OF INEBRIETY.

A reception was given by the President (Dr. Norman Kerr) and Council of the Society for the Study of Inebriety to their Associate, Dr. Henry Lansdell, the Oriental traveller, in the rooms of the Medical Society of London, on Thursday last. The President referred to the literary career of the distinguished guest, and gave a brief epitome of Dr. Lansdell's three great journeys in Asia, the last extending over 50,000 miles and occupying two years and seven months, the whole constituting a splendid object lesson for inebriates, the traveller, alike on the ice-clad Thibetan mountains, half as high again as Mont Blanc, and on the Southern plains, using no intoxicants. Dr. Geo. Harley and Surgeon-Lieut.-Colonel Evatt supported the resolution of welcome. Dr. Lansdell, in replying, referred to the quaint medical treatment among the Kirghese, and dwelt on the uselessness of alcohol as an article of diet. Subsequently there was an interesting and animated discussion on the "Opium Question," in which Sir Wm. Moore and Dr. George Harley, F.R.S., spoke strongly in favour of its dietetic use, while Brigade-Surgeon Pringle and Dr. Lansdell took the opposite view. Dr. Norman Kerr, in summing up the discussion, remarked that the proportion of opium takers who became slaves to the drug was very much higher in the Anglo-Saxon race. It was a fallacy to suppose that the great majority of takers of opium in the East were opium victims. As with alcohol in Britain, the majority were limited users, the drunkards being perhaps less than 10 per cent. Yet, after every allowance for exaggeration, it appeared to Dr. Kerr that, from a medical and scientific point of view, opium, like alcohol, could be regarded only as poisons, whose useful and beneficial employment was restricted to therapeutic use.

Correspondence.

LADY MEDICAL MISSIONARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the vast inroad of material changes which the British have made in India, and especially since the development of railways, it has inevitably followed that the Briton should desire to spread his ideas, social institutions, and culture amongst the natives. We thus see an active propaganda of Christian missions, of anti-opium efforts, and of Zenana medical missions. As to the first, the Briton ignores that we Hindus are a deeply religious people. It is true that our theologies are fanciful and extravagant; it is found that the masses of the people must have religious feeling associated with some concrete forms; we see precisely the same thing in Europe; nor are the theologies of Europe and Britain more solidly based than are ours. Modern criticism is daily proving the earlier common-base of all the Holy books of the East, from Bengal and China to the Mediterranean. The religion of India is one and indivisible with that of the purer and more exalted spirits of Europe.

Of the second propaganda, that of the anti-opium party, there is more vice in London, in one night, from alcohol, than in all India, in one year, from opium. You *cannot* prevent the native from using opium, and you are dangerously invading his social life and his cherished rights, and his legitimate pleasures, when you attempt to meddle with the use of opium in India. As the third propaganda—the presence and influence of British women in our Zenanas, I beg to say, that we consider our women far more desirable companions than are yours. It is quite true, that a noble-minded and pure British woman is a far superior being to the average of our higher-caste women; but on the other hand, our women in general are vastly superior to the "masses" of British women, and infinitely superior to the *parvenue* "ladies" who constitute the bulk of British "society." I have lived a great deal, and very intimately, with native women of all castes, in India, and I have been admitted freely to the society of British ladies, and we should abhor the introduction of British lady customs into our Zenanas in India.

If you send, therefore, lady doctors to our Zenanas, you ought to send the best and most solidly educated women of your country. No woman or man can justly appreciate India, until she, or he, have learned to love our civilisation. Natives of India will rise to a man if your doctors invade our Zenanas with speculums, tampons, Higginson's syringes, pessaries, &c., and be for ever "examining" our women. We do not desire the Hindu womens' mind excited in a degraded curiosity about her private organs. We know that women in general in Britain find a very great social employment in discussing their sexual derangements, and in visiting the doctors; we have had nothing of that as yet in India, and if you impose on us a flood of young women doctors with no full and true education, and with a dangerous and vain stain of medical knowledge, who will expend their British activity in arousing in the minds of our women new sexual vices and wants, you will be putting back civilisation, and corrupting India, rather than elevating her.

I am Sir, yours, &c.,
Ramdeen (Brahman).

London, Feb. 7th, 1894.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I decline any further correspondence with Dr. Rentoul. I have written, I trust, as a gentleman and truthfully, and have once for all given the information asked for. I can have nothing to do with theoretical conjecture or hypothetical misconceptions.

I am, Sir, yours, &c.,
C. H. F. **Routh**, M.D.

52 Montague Square, Hyde Park, W.,
February 8th, 1894.

POTABLE WATER SUPPLY FOR LONDON AND OTHER CITIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—There is a great question now of finding for London an entirely new supply of water in place of that existing. But the difficulty is enormous, and the expense must be commensurate. All the water companies must be bought out, at, say, £20,000,000; then a suitable source must be found; next a great aqueduct of many miles must be constructed, at a cost of, say, £10,000,000 more. Total, £30,000,000. Who is to pay for it all? And you must be quite sure that your source is pure and will remain so; else you might find yourself only "out of the frying-pan into the fire," and all the money wasted. Then you have no fair right to go and take the supply from some distant watershed for the sake of London and rob the existing inhabitants and those to exist hereafter of their natural and proper supply. Suppose you tapped the head-waters of the Severn, you would despoil all the inhabitants of the valley, and, perhaps, ruin the river, the quantity required for London being so very great.

No; clearly none of these things ought to be done; and, fortunately, they are not needed, since a simpler and better way can be shown which would also be almost costless. This is it. Since people can bake their own bread, brew their own beer, let them also distil at home all the drinking water they require, which would probably not exceed a couple of gallons a day in moderate households. Therefore, let every house be provided with a still as commonly as with a kitchen range. Any servant could soon learn to distil as easily as to arrange a "kitchener."

Then the companies would continue their supplies now and increase them in the future. The householder would distil daily or weekly as much as he might want for drinking, just as he always cooks the raw meat from the butcher's.

I believe no food whatever ought to be eaten raw, no water drunk unboiled. The total cost of introducing the still into houses as an ordinary kitchen fixture would, no doubt, be considerable, but "divide et impera," and only a small sum would fall upon each landlord or tenant, and that would be well laid out as a health insurance, since he would get for it an absolutely pure supply; he would disarm one of the great carriers of disease—impure water.

The question is, "Is such a plan generally feasible?" Of course it is if you can combat successfully ignorant indifference. But all who are not ignorant and indifferent might have the benefit of the plan immediately; whilst those who are in outer darkness would need, no doubt, much time for the admission into them of a little light. Such a plan as this is universally applicable, whether to towns, villages, or detached houses, great or small; and whether the existing water supply is "per company" or from wells sunk in sewage-polluted soils. In fact, it is a scheme of domestic water treatment rather than of water supply, and may claim to be regarded as a medical question of the public health. May I, therefore, hope for your assistance in making the suggestion known?

I am, Sir, yours, &c.,

James E. Huxley, M.D.

Maidstone, Feb., 1894.

Literature.

LAVERAN ON PALUDISM. (a)

This work is the chief of a series of treatises which M. Laveran has written on the subject of paludism. It deals with and summarises the investigations he conducted, and describes the malarial hæmatozoon which he discovered, which discovery may fairly be said to complete our knowledge on the genesis of paludism. At home the author's work has been recognised by the bestowal in 1889 by the Academy of Science, of the Gréant Prize by an unanimous vote.

Professor Bouchard, in his report, thus writes:—"The discovery of M. Lavaran comprises the whole pathogenesis of intermittent fever; it may be said that it has changed the pathological anatomy of the disease. In fact, the characteristic pigment of the lesions of palustral affections is effected by the parasite, and is contained in the parasite itself."

Dr. Martin's excellent translation now places this splendid monograph within the reach of all English readers who are members of this great society which has done so much for the profession.

THE NEW ENGLISH DICTIONARY, VOL. II.

We have received the concluding part of the second volume of the "New English Dictionary" which is appearing under the editorship of Dr. J. H. Murray. The first part appeared in 1884, and the magnitude of the work made its production to appear slow. Now, however, there is promise of the completion of the dictionary within a comparatively short time. The thirty-five years spent in collecting, arranging, classifying, and distributing the millions of references is telling, and probably the coming year will see the completion of volume III.

The present volume, C, includes 29,295 main words. This number does not include the combination of simple and obvious meaning which are practically unlimited.

With the exception of the letter "S," the letter C is the largest in the alphabet, and contains nearly as many words as A and B taken together, and as many as the nine smallest letters X, Z, Y, Q, K, J, N, U, V, with three-fourths of O.

The Dictionary curiously illustrates the solidarity of literature. Its progress is watched from every centre of earning in the world, and scholars from every country readily contribute to forward the great work which had its genesis in Archbishop French's love of philology.

Medical News and Pass Lists.

Ealing and the Fever Hospital.

Notwithstanding the strenuous opposition of the local authorities of Ealing and Greenford and of various interested individuals the Local Government Board have agreed to constitute Acton, Chiswick, and Hanwell a joint district for the purposes of providing isolation hospital accommodation. The question of site has yet to be decided, and strong opposition is to be offered to the application of the Joint Hospital Board for compulsory powers to acquire a site in the picturesque hamlet of Perivale, near Ealing.

The Advance of Medical Education in America.

We are asked to announce that at a meeting of the Faculty of Jefferson Medical College, held on Jan. 8, 1894, it was unanimously resolved to institute a compulsory four years' course with the session of 1895-96. This step was taken in order that the large clinical service of the Jefferson College Hospital (350 cases a day) might be utilised to the fullest extent in carrying out the desire of the Faculty to provide advanced medical education of a practical character.

The Hunterian Oration.

The Annual Oration of the Hunterian Society will be delivered on Wednesday next, 14th inst., at 8·30 p.m., in the theatre of the London Institution, Finsbury Circus, E.C. Dr. J. Dundas Grant is the Orator this year, and his subject is announced as follows:—"Aspects of Medical Life: John Hunter—Andrew Clark." The theatre will be open to the attendance of any members of the profession. The Fellows and friends of the Hunterian Society will dine together on Friday, the 16th, at Wood's Hotel, Furnival's Inn, Mr. F. Gordon Brown, President, in the chair. The President of the Royal College of Surgeons, the Conservator of the Hunterian Museum, and Mr. T. Holmes, Consulting Surgeon to St. George's Hospital, have accepted invitations to be present.

Bequests to Dublin Hospitals.

By the will of Mr. Gervas Taylor, referred to in our last, the Meath Hospital receives £5,000, the Adelaide Hospital £5,000, St. Vincent's £1,000, the City of Dublin Hospital £1,000, Sir Patrick Dun's £2,500, the Children's Hospital a like sum, and the Stewart Institution for Imbeciles £2,500.

University of London

The following is an official list of candidates who passed the recent entire Preliminary Scientific (M.B.) Examinations, alphabetically arranged:—

First Division.

Barnes, Frank
Braithwaite, Wm. D., B.A.
Carrick, Cyril Frederick
Cazenove, Wm. Reginald
Clemmow, Charles, B.A.
Clogg, Herbert Sherwell
Crofts, John Henry, B.A.
Dumas, James
Frankling, Herbert George
Horn, Arthur Edwin
Liddell, Wm. Henry Singer
Peach, William Frank
Samuel, Thomas, B.A.
Scott, Aleck Lauriston

Second Division.

Barron, Henry Thompson
Bond, Frank Fouracre
Bourdas, Ernest Clarkson
Budd-Budd, Ed. John
Clarke, Arthur Ernest
Cullen, J. A. Patrick
Durbridge, Henry
Greaves, Francis Ley A.
Martin, C. MacDermt., B.A.
Newton, Harold Turner
Parrett, Ed. Erratt, B.A.
Sandham, George, B.A.
Sass, Fred. Joseph W.
Steward, George, B.A.
Walters, Blanche Elinor
Webb, Hugh G. Stiles
Whiteside, J. Thomas, B.A.
Winn, George.

55 others passed in Chemistry and Experimental Physics, and 35 in Biology at the same meetings of the Court of Examiners.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

(a) "Paludism." By Dr. A. Laveran, Professor of Medicine in the School of Val de Grâce. Translated by J. W. Martin, M.D., F.R.C.P.E. London: The New Sydenham Society. 1893.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sendin them to the Editor

Dr. B.—It is not usual to disclose the names of correspondents. We had seen the newspaper article enclosed, and some time since referred editorially to the system inaugurated by you.

PRECAUTIONS AGAINST A POSSIBLE LIVE BURIAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—In common with many other morbid nerve sufferers, I have been haunted from childhood with the horror of possible live burial. More than one hideous incident occurring within my knowledge has taught me that the terror is not utterly groundless, and I would ask you for pity's sake to tell me what steps I can take while living to protect myself against this horrible possibility. Can I make the anatomical table or cremation, accidents of course excepted, a certainty? I should prefer the former.

I am, Sir, yours, &c.,
Morbus.

⁂ 1. Obtain the promise of the person into whose hands—the wife for instance—the body will fall after death, that it shall be cremated. 2. Insert an emphatic clause in the will that the desire to be cremated shall be carried out. 3. Leaving the body for anatomical purposes would probably be more objectionable to relatives than cremation, but you could leave instructions and provide a fee for carrying into execution the opening of an artery by a surgeon.—Ed.]

Hear Both Sides.—We have carefully read the letter of our correspondent signed thus, and are always ready to "hear both sides," but in this instance he introduces statements and discusses a subject with which our readers are not concerned. Both are matters for the British Medical Association and its journal.

Dr. C. R. J.—Your letter is founded on a wrong hypothesis. The General Medical Council has no jurisdiction, even assuming the practice to be illegal. It would therefore be useless to insert your communication.

POWELL'S BALSAM OF ANISEED.

The Judge of the Bloomsbury Court decided last week that this nostrum is a poison within the meaning of the law, and cannot be sold by any one but a qualified pharmaceutist, and under the precautions imposed by the law.

Meetings of Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 14TH.

Laryngological Society of London (20 Hanover Square, W.).—At 5 p.m., Dr. Clifford Beale: Tubercular Tumour of Larynx.—Mr. Butlin: Tumour of the Thyroid Gland.—Dr. Wm. Hill: Case showing so-called "Cleavage of the Middle Turbinated."—Dr. Felix Semon: Pharyngeal Ulceration of Doubtful Nature in a case of Arrested Pulmonary and Laryngeal Tuberculosis.—Dr. Scanes Spicer: Unilateral Laryngeal Infiltration and Œdema of Undetermined Nature.—Dr. Hale White: Case of Gumma over the Arytenoid Cartilage.—Dr. Willcocks: Gummata of Epiglottis.

Huntarian Society.—At 8.30 p.m., Annual General Meeting: Election of Officers. At 8.30 p.m, Dr. J. Dundas Grant: Aspects of Medical Life—John Hunter, Andrew Clark.

London Post-Graduate Course.—Hospital for Consumption, Brompton, at 4 p.m., Mr. R. J. Godlee: Subdiaphragmatic Abscess.—Royal London Ophthalmic Hospital, Moorfields, at 8 p.m., Mr. R. M. Gunn: Cataract.—Hospital for Skin Diseases, Blackfriars, at 1 p.m., Dr. Payne: Acne.

Royal College of Surgeons.—At 5 p.m., Professor C. B. Plowright: The Fungus Kingdom.

West London Hospital (Hammersmith).—At 5 p.m., Mr. Swinford Edwards: Carcinoma of the Rectum. (Post-Graduate Course).

THURSDAY, FEBRUARY 15TH.

Harveian Society.—At 8.30 p.m. Cases shown by Mr. D'A. Power, Mr. Lockwood, Dr. Boxall, and others. At 9 p.m. Dr. W. R. Dakin: Modern Methods of Treating Post-partum Hæmorrhage.

Society of Anæsthetists (20 Hanover Square).—At 8.30 p.m., Discussion on the Administration of Anæsthetics in Operations upon the Nose and Throat. Mr. Bailey, Mr. Braine, Mr. Tyrrell, Dr. Buxton, Dr. Hewitt, Mr. Davis, Dr. Silk, and others.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street, at 3.30 p.m., Mr. C. A. Ballance: Clinical Lecture.—National Hospital for Paralysed, Bloomsbury, at 2 p.m., Dr. Ormerod: Hemiplegia.—Central London Sick Asylum, Cleveland Street, W., at 5.30 p.m., Dr. Patrick Manson: Malarial Disease.

FRIDAY, FEBRUARY 16TH.

London Post-Graduate Course. — Hospital for Consumption, Brompton, at 4 p.m., Dr. E. Symes Thompson: Phthisis and Life Assurance.

Royal College of Surgeons.—At 5 p.m., Professor C. B. Plowright: The Fungus Kingdom.

SATURDAY, FEBRUARY 17TH.

London Post-Graduate Course.—Bethlem Hospital, at 11 a.m., Dr. Percy Smith: Climacteric and Senile Insanity.

MONDAY, FEBRUARY 19TH.

Royal College of Surgeons, England.—At 5 p.m., Prof. E. T. Collins: The Anatomy and Pathology of the Eye.

St. John's Hospital for Skin Diseases (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Ulerythema and Sycosis.

Vacancies.

Coombe Lying-in Hospital, Dublin.—Assistant Master. Applications to the Master. (See advert.).

County Lunatic Asylum, Snenton.—Assistant Medical Officer (unmarried). Salary £100 per annum, rising £10 annually to £150, with board, lodging, washing, and attendance. Applications and testimonials to the Chairman of the Committee of Visitors on or before Feb 27th.

Cumberland Infirmary, Carlisle.—Assistant House Surgeon. Salary £40 per annum, with board, lodging, and washing. Applications and testimonials to the Secretary on or before Feb. 21st.

Dublin - Cork Street Fever Hospital.—Resident Medical Officer. Salary £65 per annum, with maintenance. (See advert.).

East Suffolk and Ipswich Hospital.—House Surgeon (unmarried). Salary £80 per annum, with board, lodging, and washing. Applications and testimonials to the Secretary on or before Feb. 20th.

Guildford and Godalming Joint Hospital Board.—Medical Officer. Salary £175 per annum. Applications and testimonials to the Clerk to the Joint Board on or before Feb. 19th.

Leeds.—Hospital for Women and Children.—House Surgeon. Salary £75 per annum. Applications to the Secretary.

National Orthopædic Hospital, London.—Assistant Surgeon. Must be a F.R.C.S. Eng. Applications to the Secretary. (See advert.).

Queen Charlotte's Lying-in Hospital.—Resident Medical Officer. Salary £60 per annum, with board and residence. Applications and testimonials to the Secretary on or before Feb. 20th.

The Hospital for Women, Soho Square, London.—House Physician. Salary £30 for six months, with board, &c. Applications and testimonials to the Secretary on or before Feb. 21st.

Whittingham Asylum, Preston.—Junior Assistant Medical Officer. Salary £100 per annum, with board, &c. Applications to the Superintendent on or before Feb. 23th.

Appointments

Bartlett, R. C., M.R.C.S., L.R.C.P., House Surgeon to the Dorset County Hospital.

Bishop, H. D., M.R.C.S., L.R.C.P. Lond., Senior House Surgeon to the Carnarvon Hospital, Kimberley.

Blaxall, F. R., M.D. Lond., D.P.H. Camb., Lecturer on Bacteriology to the Westminster Hospital.

Etohes, W. R., M.R.C.S., L.R.C.P. Lond., D.P.H., Medical Officer of Health for the Macclesfield Urban Sanitary District.

Hope, E. W., M.D., C.M. Edin., L.R.C.P. Lond., Medical Officer of Health for the Liverpool City and Port.

Johnson, W. J., M.B., B.S. Lond., M.R.C.S., L.R.C.P., Assistant House Surgeon to Guy's Hospital.

Laverick, J. V., L.R.C.P. Lond., L.F.P.S. Glasg., L.R.C.P. Edin., Medical Officer of Health for the Whitby Rural Sanitary District.

Leathe, J. B., M.B., B.C. Oxon., Assistant House Surgeon to Guy's Hospital.

Macintosh, W. A., M.D., Medical Officer to Simpson's Asylum, near Bannockburn.

Milne, A. D., M.B. Aberd., House Surgeon to the Children's Hospital, East End Branch, Sheffield.

Ricketts, T. F., B.Sc. Lond., M.D., Medical Superintendent of the Hospital Ships of the Metropolitan Asylums District.

Sheperd, A. W., L.R.C.P., L.M., L.R.C.S. Irel., Medical Officer of Health to the Cowbridge Town Council.

Uthoff, J. C., M.D. Lond., M.R.C.P., F.R.C.S., Honorary Surgeon to the Sussex Eye Hospital, Brighton.

Wickham, G. H., M.B., B.C. Cantab., Honorary Medical Officer for Out-patients, Royal Victoria Hospital, Bournemouth.

Wilson, H. B., M.R.C.S. Eng., Health Officer to the Shire of Frankston and Hastings, Victoria, Australia.

Wylie, R. J., M.B., C.M. Glasg., Medical Officer for the Third Sanitary District of the Hertford Union.

Births.

Dove.—Feb. 6th, at Parkside, Crouch End, the wife of Augustus C. Dove, M.D., of a son.

Mears.—Feb. 11th, at Atherstone, Warwickshire, the wife of Robt. Mears, L.R.C.P., M.R.C.S., of a son.

Williams.—Feb. 7th, at Salisbury House, Tottenham, Middlesex, the wife of J. Lawson Williams, M.B., C.M., of a son.

Marriages.

Hay—Bodington.—Feb. 3rd, at the Cathedral, Lichfield, Robert Hay, M.D., Royal Navy, to Juliet Eaton, eldest daughter of G. F. Bodington, M.D., F.R.C.S. Eng., of Hatzie, British Columbia.

Deaths.

Clark.—Feb. 8th, at Kirklands, Bothwell, N.B., Jessie Gowenlock, wife of Archibald Campbell Clark, M.D.

Fox.—Feb. 4th, at Ardgowan Square, Greenock, N.B., John Fox, M.D., formerly of Corliamore, Co. Cavan.

Lawson.—Feb. 9th, at Aberdeen, Robt. Lawson, M.D., Inspector General of Hospitals, Hon. Phys. to the Queen.

Nicholas.—Feb. 9th, at 3 Church Row, Wandsworth, Geo. Ed. Nicholas, M.D., M.R.C.S., Medical Officer for Wandsworth District, aged 69.

Roberts.—Feb. 5th, at his residence, Aberdare, Evan Vaughan Roberts, M.B. Edin., aged 30.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

Clinical Lectures

ON SOME

OBSCURE AFFECTIONS OF THE LUNG.

Delivered at the London Hospital.

By the late SIR ANDREW CLARK, Bart., M.D., F.R.C.P., L.L.D.,
President of the Royal College of Physicians, London.

LECTURE III.

GENTLEMEN,—On a former occasion I discussed with you the relationship of certain conditions of the lungs and pleura with the results of physical examination, and incidentally I pointed out two entirely distinct classes of lung affections which have erroneously, in my opinion, been classed as tubercular. I now bring before you another patient whose case will serve to carry us a step further in the consideration of some of the more obscure affections of the lungs. Our patient this time is a young girl; she is thin, though not amounting to emaciation. She has a small pinched face that tells of past privations in spite of the fact that its outlines have in large part been restored by careful feeding since she entered the hospital. Now, if we look at her chest before proceeding to investigate the condition of the thoracic viscera by the usual means, we see at once that the chest is smaller on the left side than on the right, and that the respiratory movements, as you can all see, are distinctly less ample on that side than on the right; in other words the left chest expands on inspiration less completely than the right. On percussion you will notice that the note is dull in front and behind on the left side, the dulness increasing in degree as we percuss lower down the chest wall. On making her speak I perceive, moreover, that tactile vocal fremitus is far less evident on the left side than the right. On auscultation, beginning with the back of the left lung, we find that at the top the breath sounds are fairly normal, but as we descend they become feebler and feebler, as well as hollower, and vocal resonance diminishes progressively. At the very base the breath sounds are quite inaudible, and there is no vocal resonance at all. The same holds good in the axillary region; above, the lung appears normal; below, the breath sounds are feeble, and vocal resonance is wanting.

Now you see that, though the patient seems and feels quite well, there may be a good deal of disease present in the lung. Indeed, in this case, as you have seen, it involves more than a third of one lung.

On examining the right side as a matter of routine, we find that the respiratory sounds and the percussion notes are normal throughout. The heart is acting slowly, steadily, and firmly; there is nothing to be said against it, although, as we shall shortly see, it is displaced outwards. The pulse is good, there is a good volume of blood passing through the radial artery, especially if we consider the circumstances under which she now finds herself. The position of the heart's apex is the next thing to be ascertained and considered. This we find without difficulty is not in the usual place. It has been drawn or pushed outwards, and this, as I proved to you, in a preceding lecture, is a point of the very greatest significance. There is obviously something wrong with the left lung, of which one effect has been to displace the heart. Nowhere else can we find evidence of anything wrong. Now, what are we confronted with? What is the meaning of it? What is its past history, its future? To begin with, what is wrong? There is displacement of the heart, which is beating in the left axillary line. It must have been pushed or pulled over there. It cannot have been pushed there, for I have shown that the right lung is quite healthy, while the left lung is to a great extent solid. It is, indeed, not only consolidated, but is diminished in bulk. Now, two things may occur with a lung that is contracted at the base which may mislead us. The front may become emphysematous, and so give a good percussion note or, on the other hand, the stomach may be pulled up out of its place, and so pave the way to errors of diagnosis in the hands of the unwary. We have discovered that the lower part of the left lung is solid, indurated, contracted, and whatever may be the nature of the changes it certainly is of a kind that has created no constitutional disturbance, and which, moreover, has caused no local disturbance in the immediate neighbourhood. What can it be? All that I can say, looking at the case with these symptoms before us, and assuming that I know nothing of it except what I have demonstrated to you, is that here is a young girl with a solid contracted lung at the base. How do I know, first of all, that there is no actual disease in progress? Of this one cannot be absolutely sure, but this, at least, we may affirm, that there is no evidence or intimation of constitutional disturbance. All the functions of the body are being performed in a satisfactory manner, there is no fever, no quick breathing, no wasting that cannot be otherwise explained, no loss of strength or health, no incapacity for the daily routine of labour to which she is accustomed. It is almost impossible to conceive that under such circumstances the disease can be actually progressing. It would be impossible to get physical signs of this kind and extent unaccompanied by constitutional disturbance if the disease were progressing. This being the case, the lung affection being quiescent, we have to ask ourselves how it came there? In answering this question the past history is all important, and it happens that I can go a long way back and tell you something about this girl's past history. She was admitted on December 14. Her occupation is that of machinist, she lives in a room where many others of her family live, and she works in a room where many others besides herself work. She thus lives and works in rooms in which it often gets close and oppressive, so that both at home and at work she is placed under conditions most disadvantageous to health. The story of those who, like this girl, are so placed, is very interesting, and I begin by telling you these details because her family history exhibits no tendency to hereditary disposition to pulmonary disease. However she came by this affection of the left lung she clearly did not inherit it from her immediate ancestors. She was brought to us on December 14th, not on account of anything the matter with her chest, but complaining of pain in her leg and hip. We examined her lungs as a matter of course, and we found there what you have all found to-day, neither more nor less. We found evidence of old mischief. She had not been long under observation, however, before the interest of the case was materially increased by the supervention of signs of inflammation in the affected part of the left lung. Her temperature began to rise, and with the fever came some shortness of breath. By-and-bye we discovered patches here and there of consolidation scattered over the left lung. These, however, soon cleared up, and the pain in the leg and hip having subsided, we were flattering ourselves that her trouble was over, and were about to let her leave the hospital, when one day she suddenly had a relapse, and then not only did the patches of consolidation reappear, but small pleuritic rubs could be heard, and coincidently therewith small areas of consolidation were established on the right side as well. The constitutional disturbance became more marked, the cough became incessant, the expectoration frothy, and, almost daily, fresh areas of consolidation could be detected in various parts of the right lung both in front and behind. Then we had to ask ourselves, what is the disease with which we are dealing? It looked very much like phthisis, tubercular phthisis, for it must be borne in mind that she is a strumous girl, she had disseminated deposits all over the left lung, and, without rhyme or reason, similar deposits were forming in the right lung. We examined the expectoration in order to ascertain whether or not tubercle bacilli were present—not that we were going to pin our faith on a bacillus—but simply because their presence would have been a matter of interest, and might assist us in elucidating the nature of the affection. As a matter of fact, the most careful and repeated search failed to reveal any bacilli. The patient was treated with a moderate amount of stimulants, and was given citrate of iron and quinine. I concluded that she was the subject of a disseminated caseous pneumonia, and I expressed the opinion that she would ultimately recover. It was to some extent rather a bold diagnosis, and an even bolder prognosis, because most of those about me were of opinion that it was a case of tubercular phthisis. Bit by bit, however, the deposits in the right lung cleared up, the friction sounds became inaudible, and before very long the right lung was quite free. The left lung, at the base of which there was some kind of mischief before she came into the hospital, progressed more slowly, but it did progress towards recovery, and she left the hospital in April of last year apparently in good health. She is now in the same condition as she was before she had the mysterious pain in the hip and leg along with the curious attack of double pneumonia. Now the account of her case so far is very clear. She has a contracted lung, she has had a pneumonia, probably of the caseous variety, and she presents herself to us on this occasion with traces of some old-standing disease in the left lung. We must go back still further. We have still to ask the question, what was it that originally begot this dull contracted lung which she now has? Looking at her age and history, it must have been one of two things—either she must have had a pleurisy or a pneumonia, that is to say, at some time during her life she had an ordinary basic pneumonia which did not undergo complete absorption, and the portion of lung in which absorption thus failed to take place gradually underwent contraction. I think, looking at her history, that it is infinitely probable that she had a pleuro-pneumonia, an inflamed base of the lung with an inflamed pleura around it. This was probably not all absorbed, the exudation remained and underwent fibroid degeneration, which has persisted, and will persist, as long as she lives.

Now comes another question, might it not be phthisical? I have already said that there can be no disease of a progressive character in the absence of some evidence of a constitutional disturbance. Moreover, you never get one-third of a lung affected in phthisis without the other lung being implicated. Here then is the practical question. What is likely to be the future history of this case? We have already got an inkling of what it may be. She had this affection of the left lung before her last illness, and one of the disadvantages of having a consolidated lung is that it renders that lung, and perhaps the other too, more vulnerable, much less strong to resist the causes of disease, much less ready and apt to repel them, so that this girl with that consolidated lung is at a serious disadvantage in the struggle for existence, not so much from the mere presence of the consolidation as from the fact that it renders her more prone to disease than she would otherwise be. Now the future of the case depends upon two things, first upon her general health, and secondly upon the mode in which she deals with slight colds. First as to the general health. Everything that can be done to raise the standard of the girl's health is in her favour, for it will give her increased powers of resistance to the causes of inflammation and increased powers of repair should occasion arise. What then are the conditions of health for her? She is a strumous child, so you must feed her four times a day. For breakfast she should have bread and butter, weak tea, with eggs or bacon. Strong tea and coffee should be avoided, especially early in the morning. She is a nervous girl, and they would tend to unnerve her still farther. I may remark incidentally that it has always been a matter of surprise to me how it is that we English people do not suffer more than we do from our indulgence in tea, especially tea prepared as it usually is, and taken after a prolonged fast early in the morning It is a great and powerful disturber of the nervous system, and no one who has any regard for the integrity of his or her nervous system would take it that way. Its immediate effect may be all that can be desired. It relieves the *malaise* which is in itself a sign of warning, and it thus enables the consumer to disregard it. Beware gentlemen of thus sitting on the safety valve. Nature provides a warning in most cases of impending disaster, and if you wilfully disregard or stifle them you do so at your peril. This pernicious habit of taking strong tea after a night's fast, repeated day after day, week after week, year after year, leaves its stamp on the nervous organisation of the individual, and this stamp is handed down, in part at any rate, to the generation that follows. The reflection is one which may well inspire apprehensions as to the nervous fate of future generations.

To return, however, to the feeding of our patient. She should have a good dinner with meat, and she should drink water. I have no objection to a moderate amount of alcohol, but for this girl who is nervous the less she takes of things which play on her nervous system the better. Finally, tea, with perhaps a light supper. Let her food be as good and as fresh as possible, and let her take nothing between meals. Then she ought to take a walk twice a day, and I would endeavour to modify the general conditions of existence so as to render them more conducive to health. I cannot disguise from myself and from you the fact that this poor girl was born in and to conditions most injurious to her, but out of which she cannot get. She works with twenty or thirty other girls in a room in which, for the greater part of the day, gas is burning, and she goes home to roost in an atmosphere which has been contaminated by domestic and other emanations. Yet after all the girl may survive and grow up a fairly healthy woman. These poor people have a curious way of struggling through trials which would prove fatal to persons better provided with the good things of this world.

I would warn her, in conclusion, of the gravity of chills and colds, and the necessity of promptly attending to anything of the kind. If she ever neglects this salutary precaution, a neglected chill will place her in imminent peril of a fresh attack of inflammation which may be less easily repaired and subdued than her last attack, and then it is quite possible she may, in a sense, become a phthisical person.

NOTES ON DEFORMATIONS OF THE GENITAL ORGANS,

PRACTISED BY THE NATIVES OF AUSTRALIA. (a)

By. J. G. GARSON, M.D.

The following notes on deformations of the male and female genital organs practised by the Aborigines of Australia may not be uninteresting to the Fellows of this Society. The information which I am about to communicate was collected and sent to the Anthropological Institute by Mr. B. H. Purcell, a gentleman who has, for the last 25 years, given great attention to the study of these natives amongst whom he resides.

Circumcision.—This operation is practised all over Australia, except in Victoria and New South Wales, on boys at the age of eight years. The operation is performed by one man seizing the prepuce between his forefingers and thumbs and stretching it to the fullest extent, while the head man of the tribe transfixes it with a flint knife of lancet shape, sharpened on both sides, and cuts it off with one circular sweep. After the bleeding has ceased the wound is dressed with the soft down of a duck or the eagle-hawk.

The Mylagoordi have a somewhat different method of performing the operation. They divide the prepuce by four longitudinal incisions and then dissect each segment backwards "to the butt of the penis," removing each separately.

In the Northern territory the prepuce is scored with a flint knife and is then dressed with irritating herbs so as to produce hypertrophy of the parts.

The operation is done for the purposes of cleanliness. The natives do not consider a person clean unless he has been circumcised, and a circumcising tribe will not eat food with one who is uncircumcised.

A *Mika* is a man upon whom an operation to produce artificial hypospadias has been practised for the purpose of preventing him from having any family. Three different operations are performed for this purpose.

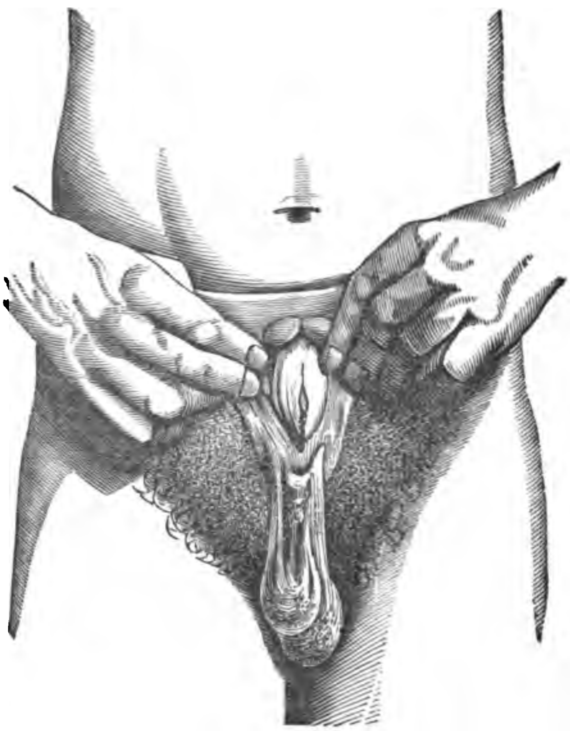
1st.—On Corpus Christi Creek, Western Australia, the natives content themselves with making a small incision through the urethra immediately in front of the scrotum. Through this opening the semen is ejaculated during copulation, after the wound is healed.

2nd.—On the Diamantina and Lower Georgiana the natives divide the urethra in front of the scrotum and again just below the glans penis, then cutting longitudinally along each side of the urethra dissect it out.

3rd.—The most general plan of mutilation is that of which I show you a photograph. It is performed by placing a narrow piece of wood along the dorsum of the penis and drawing the loose skin tightly backwards over the wood. A flint knife is then inserted into the orifice and the urethra is laid open to the scrotum. Before the operation is performed the penis is beaten till it is benumbed. After the operation the penis is bandaged against the abdomen; should excessive inflammation of the wound occur during the healing process it is dressed with a kind of native clay or crushed eucalyptus leaves. The mortality after this operation is stated to be *nil.*

These operations are performed on youths at the age of 18 years, and only upon a certain number of them, namely, those who prove themselves indolent and the least useful members of their tribes.

A *Euriltha* is a woman upon whom the following operation has been performed for the purpose of rendering her barren:—



A roll of emu feathers is made, seven or eight inches long, thinner at one end than the other, it is lashed round with twine manufactured from opossum fur, and daubed with a mixture of fat and red ochre. To the smaller end a cord, made of human hair, is attached, looped over it, and brought down to the thicker end. The girl, who is between 10 and 12 years of age when the operation is performed, is placed upon her back, and the thin end of the roll with the loop is inserted into the vagina. With a flat piece of stick passed up the vagina along side of the roll the loop at its upper end is placed round the projecting end of the cervix uteri. The girl is watched for a while till the parts have become swollen, the free end of the cord is now twisted round the hand of the operator and the portion of the cervix included in the loop is forcibly severed and drawn out with the roll and loop. The girl is placed in camp for the next three weeks. At the end of that time a small flint knife, fixed to the end of a stick six inches long, is passed up the vagina and a vertical and transverse incision is made in the stump of the cervix. These incisions are then stuffed with down of the duck or eagle-hawk to keep them open, lumps of heated fat are now inserted to grease the parts and keep them clean. When the wounds have healed, the lower end of the posterior wall of the vagina is divided down to the anus, so as to make sexual intercourse with the Mikas more easy. The operators are the old men and women of the tribe.

This horrible operation is only practised by a few tribes in Central Australia. It has often been called spaying, but Mr. Purcell says "I have examined all the women of the tribes where these operations are done, but on none of them did I find a trace of the flint knife for spaying." Instead of performing the whole operation the natives content themselves with dividing the lower part of the posterior wall of the vagina.

(a) Read before the Medical Society of London, Feb. 5th, 1894.

Women on whom only this part of the operation has been done are called a Dindahs or Dindees.

◆

THE AERIAL CONVECTION OF SMALL-POX FROM HOSPITALS. (a)

By J. C. McVAIL, M.D.

In opening the discussion on the possible influence of small-pox hospitals in aerially conveying the disease to surrounding population, let me state *in limine* that my purpose is rather to review existing knowledge than to adduce new facts, unless, indeed, some facts to which I wish to draw attention are so very old as to be entirely new to any of the members of the Epidemiological Society. For it is a trite saying that history repeats itself, and even in regard to the discussion of this subject the saying holds true.

The author proceeded to discuss the correspondence which took place a century ago between the celebrated Dr. Haygarth of Chester, and Dr. Waterhouse, Professor of Physic in the University of Cambridge in New England, on this very question, and some of the points then raised were not without interest to us in the present day.

Further, he said, one or two instances have struck me particularly in reading the more recent literature that has grown up around this question. The dustman of one of the Metropolitan Asylums Board hospitals caught small-pox, and though doubtless removed to hospital immediately on the disease declaring itself, he yet succeeded in infecting members of his own household. These people, therefore, were susceptible to small-pox. But, for years before, that dustman had been going in and out of the hospital carrying on his work of refuse removal there, and in and out of his own home, yet he had never brought infection within his doors till he himself was seized with the disease. Similarly, in the course of the Fulham inquiry, no case was found of small-pox occurrence in the houses visited by officers and servants of the hospital, and nine non-resident servants did not carry the disease to their houses in nine different streets. Again, in considering one particular group of cases thought to be due to aerial convection, Mr. Power tried to exclude all as to which personal conveyance could be in the least suspected. One excluded case was that of a man who had had a drink in a beershop along with the driver of an ambulance waggon. How many other people may have been drinking at that time, or on other journeys, along with this driver, and yet not have been infected by him?

This question of the influence of ambulances in spreading the disease around hospitals was before the Commission of 1881 at some length. On one hand it was in evidence that the service was sometimes badly managed; that the driver might stop at a public-house on the way; that children might hang on behind the van. On the other hand it happened that some ambulance routes were pretty well fixed, especially near the hospitals, and that in the streets regularly traversed by them there was no special prevalence of the disease. This fact is noted not only regarding Fulham Hospital, but also by Dr. Bristowe as to Deptford Hospital; indeed, examination of details seems to show that the quadrant of the mile circle, containing the chief line of human intercourse with Fulham Hospital, chanced in 1881 to have a smaller percentage of its houses attacked by small-pox than any of the other three quadrants. It is true that people living in one street might encounter the ambulance in another, and go home and lie down with the disease a fortnight later. But it is equally true that on any sufficient basis of facts a larger proportion of people belonging to the streets traversed by the vans would be exposed to the ambulance influence, than of people belonging to other streets. And in regard to those who met the van in one street and lived elsewhere, it would be a very extraordinary thing if the houses to which these people returned happened to be arranged in number diminishing regularly according to the distance from the hospital to which the van was travelling. It would be still more extraordinary if this same regularity of arrangement were found to repeat itself around the same hospital in epidemic after epidemic. It is a remarkable fact that one witness who maintained the view that hospitals were not centres of infection, either aerially or by personal transmission, pointed in support of his thesis to one street in particular, a lane only 10 feet wide, closely adjoining Homerton Hospital, and forming a passage for nearly all the ambulances that entered its gates. There had been only one small-pox death belonging to this street in the decade 1871-80; but, on turning to the number of inhabitants attacked in this thoroughfare, I find from Dr. Tripe's figures that they amounted to 13 per cent. of the average total of inhabitants, a proportion which, in comparison with that of the adjoining streets through which the ambulance did not habitually pass, was higher than some and lower than others.

Similarly, it was pointed out that some of the persons attacked within the "special area" surrounding the hospital might have got their infection in other parts of London to which their daily avocations took them. This is so; but again, is it likely that these people would come home and settle themselves down in regularly decreasing circles around the small-pox hospital? It is not to be denied, however, that, excluding ambulances which had pretty clearly defined routes of traffic to the hospital, and excluding introductions of the disease from other parts of the Metropolis, such small-pox as depended on personal communication from the hospital would tend to range itself in radii corresponding to the lines of communication with the hospital, the amount increasing with the distance. And I do not for a moment suggest that personal conveyance of one sort and another had not a great deal to do with the matter. Here, as elsewhere, many groups of cases would be secondary to, and directly connected with, foci outside of the hospital, and it is in no way surprising that evidence of conveyance of this sort was able to be put before the Commission. But such foci, unless the mischief done by them was always equal, might tend rather to disturb than to emphasise gradation from centre to periphery. And it appears that in the locality around Fulham Hospital practically all cases were sent to hospital after their discovery. It has never been suggested, however, that aerial convection excludes personal communication, or that the area around the hospital forms an unsuitable field for the latter method of spreading the disease. The question is, Is personal communication the likeliest way to account for *all* the facts?

Coming now to the subject of aerial convection, both in Waterhouse's time and more recently, various theoretical considerations have been adduced with regard to the possibility of the survival of infective power through the requisite space for the requisite time. The distance to which an animal odour like the smell of the skunk can be carried, and the phenomena of hay fever, are instances in point. Too much value may easily be attached to such analogies, and they might be used in support of a thesis that measles, or whooping-cough, or typhus, can be conveyed for long distances. I may note, however, that Dr. Waterhouse quotes from Dr. Aspinwall to the effect that "it is a fact well known to every ploughboy, that a skunk can be smelt much further in a dampish, foggy evening than in serene weather." The length of time during which a lancet charged with small-pox matter can retain its inoculative power is more to the purpose, but very exact and careful observations would be needed to give evidence of value here. All we seem to know is, that certain animal emanations are not affected by long travelling through the atmosphere, but whether or not this is true of small-pox under any circumstances is a question that must be settled by evidence. And there may be very important distinctions between the length of duration of the quality of smell by non-living material, and the length of duration of powers belonging to what current pathology teaches to be a contagium vivum. Probably, however, Sir Thomas Watson fairly represents the consensus of opinion in his own day when he says, "There is no contagion so strong and sure as that of small-pox, none that operates at so great a distance."

In his evidence before the Commission, Sir John Simon, with characteristic caution, stated that, while he attached great weight to the evidence already produced in support of aerial convection, he would wait for further confirmatory evidence. This requirement has to a great extent been fulfilled. As a result of the original inquiry, and of the work of the Royal Commission, Fulham Hospital was put on its mettle. Those in charge of it knew how much might depend on their success or failure in preventing the spread of infection by personal communication, and we need not doubt that no stone was left unturned in the endeavour to prevent subsequent confusion of issue. The outgoings of the staff were reduced to a minimum, and increased stringency was observed in every detail. Yet, when the next outbreak occurred in 1884-85, the result was practically as before. All the extra care taken failed to lessen the incidence in the special area per hundred admissions of acute cases to the hospital. Indeed, the number of acute cases within it was remarkably small, when, in the presence of weather conditions resembling those formerly noted, a "special area" outburst occurred. It was further observed, however, that these meteorological conditions, repeating themselves subsequently, were not always accompanied by increased infection around the hospital. In view of such facts, it is obvious that there is still much to learn regarding the whole question, and it is open to us to speculate whether the rhythm of epidemic and non-epidemic periods includes, as by analogy we may easily believe it to include, lesser rhythms of ebb and flow of infectivity, having to do not with seasons, but with weeks or days. In this aspect of it, such special outbursts as have been noted might be looked on as spring-tides of infection.

(a) Paper read before the Epidemiological Society, Jan. 17th, 1894.

From October, 1884, a part of Fulham Hospital not previously used for scarlet fever came to be devoted to that disease. The management, as regards laundry, nurses, and servants, was quite separate from that of the small-pox wards, the only official in common being the medical attendant, who, of course, was well aware of what had been alleged regarding personal communication, and who, we may assume, was correspondingly careful. In the fortnight ending December 6th, following the opening of these scarlatina wards, there was great increase in the admission of acute cases of small-pox, and excessive spread of the disease in the special area. At this time, four cases convalescent from scarlet fever were attacked by small-pox, and all the others were at once revaccinated. These four cases constituted 10 per cent. of the total scarlet-fever cases. But no small-pox case was attacked by scarlatina, and it is noteworthy that the hospital did not act as a centre for the spread of scarlet fever or typhus or any other disease in the special area. We know very well that these diseases, and especially scarlet fever, can be conveyed by personal communication; but, as a matter of fact, the administrative procedure of the hospital did not spread even scarlet fever. And if it be replied, that perhaps small-pox is conveyable further and more surely by fomites than is scarlet fever, the comment is obvious, that in that case small-pox is likely also to be further conveyable atmospherically.

In conversation recently with Dr. Ernest Marsh, who had charge of the small-pox wards at Belvidere Hospital during the past year, I was informed that one scarlet-fever ward had its windows 48 feet from the nearest small-pox ward, and that the only one of the scarlet-fever patients whose vaccination was neglected to be attended to, was a little American boy who had never been vaccinated, and who straightway was attacked by severe small-pox. The administration here was entirely separate, even as to medical attendance, and a barricade 13 feet high separated the one part of the hospital grounds from the other. Similar instances of aerial convection measured by feet are not uncommon, and the facts are, of course, much more easily proved than where hundreds of yards are in question. Dr. Septimus Gibbons mentioned to the Commission a case in which a distance of 20 yards intervened; Dr. Richardson a case of 30 feet; and Dr. Munk a case of 41 feet, and so on. And long before the theory of distant aerial convection was formulated, Drs. Gregory and Marson, of the original Small-pox Hospital, strongly insisted on a belt of 150 feet around the hospital, and their successor, Dr. Munk, supported the same view before the Commission.

I have already incidentally mentioned, as part of the thesis of aerial convection, that it depends on acute cases, not on convalescents. Probably it will not be denied that personal communication, both of scarlet fever and of small-pox, is likely to occur during desquamation in the one case, and the separation of the crusts in the other. But one of the earliest facts ascertained as to Fulham Hospital was that when it was devoted entirely to convalescents who were conveyed there in large numbers under the same ambulance arrangements as were criticised when acute cases were in question, small-pox did not spread in the special area. At that time the outgoings of servants and visitors and tradesmen were singularly powerless. At Darenth Hospital 600 convalescents failed to spread the disease. As with regard to distance, so with regard to limitation of admissions of acute cases, there is observable a tendency to give effect to the thesis while not formally adopting it. Various witnesses mentioned various numbers to which they would restrict the totals of cases under treatment in any hospital. Of mixed cases, such figures as 150, or 100, or 80 were given; and of acute cases, one said 50 or 60, another 20, and so on, and in later epidemics the numbers in the Intra-Urban Hospital were limited first to 50, afterwards to 25, and finally small-pox was altogether excluded from them.

The above are the main points that have impressed themselves on me as supporting the view that small-pox may sometimes be aerially conveyed to a relatively long distance. It is not my purpose to do more than refer to the confirmatory evidence recently yielded by the outbreaks in Oldham and Warrington as recorded by Drs. Niven and Gornall. Probably here, as elsewhere, both agencies may have been at work, but it is certainly of consequence that these observers have not been able to account for some of the facts that came before them unless by acceptance of the atmospheric theory.

In the course of his Report for 1893 Dr. Niven says:—"Is this increased incidence round Westhulme Hospital due to aerial diffusion, or to faulty administration of the hospital, leading to direct contact between the untraced cases, and the officials of the hospital a fortnight before their attacks? I may say at once that I am satisfied that no such contact has taken place. Whether in isolated instances small-pox may have been caught by coming too near the hospital it is difficult to say. For the most part that possibly could be excluded." Dr. Gornall says:—"The statistics as to the relative incidence upon the specially afflicted area and its several parts most clearly agree with what we should expect with *air-borne infection* as to the explanation of our difficulties."

As to foreign evidence, a paper by Sir John Cormack, in the *Edinburgh Medical Journal* for 1881, shows that in Paris facts more or less similar had been observed in connection with hospitals there.

Of the arguments urged against the theory, by far the most striking is that regarding the incidence of the disease on certain institutional populations within the special areas. These, indeed, claim to furnish a series of control experiments in which absence of small-pox was suggested to be due to absence of personal communication as a result of careful administration. One of the members of the Royal Commission put the case very strongly to a witness who inclined to support the theory of aerial convection. He referred to "the fact that in some cases workhouses are actually overlooking the grounds of a small-pox hospital with actual immunity from small-pox."

Similarly, Dr. Dudfield in his evidence said:—"You know the case of Homerton Hospital, which is from 90 to 100 feet distant from the City of London Infirmary, in which no case of small-pox has occurred since the hospital has existed: that is a case which I have very much relied upon myself, and I know it has had great weight with my colleagues, the medical officers of health." And with reference to the same institution, the Commissioners stated in their report that "the workhouse had scarcely any case in the epidemics of 1871-77 when the disease was extremely prevalent in the surrounding streets, although at that time the inmates were not protected by re-vaccination. The same may be said of the Hackney Union Workhouse and Infirmary, which are about a quarter of a mile from the Homerton Small pox Hospital."

The strength of the argument thus set up against aerial convection is so obvious that it is of importance to look into the details of the facts on which the argument is based. The institutions in question were of two classes, workhouses and Poor-law infirmaries, the former being capable of much more thorough protection against personal communication than the latter. Eight of such institutions were mentioned, four being about half a mile from Fulham Hospital; one about a quarter of a mile and another about 200 feet from Highgate Hospital; one (Hackney Workhouse) about a quarter of a mile and another (the City of London Workhouse) about 100 to 200 feet from Homerton Hospital. No details are given as to the institutions related to Fulham Hospital, but, as the distance was considerable, this absence of information is of less consequence, especially as the fullest statement of facts has to do with the institution which was nearest to a small-pox hospital, viz., the City of London Workhouse adjoining Homerton Hospital. In Dr. Bridge's Report of January, 1881, re-published by the Royal Commission, he wrote:—"I have made careful inquiry for any case of small-pox occurring in this Workhouse during the present or previous epidemics among the inmates, but I have only been able to find one, and this one not attributable to the hospital." It seems likely that this statement may have been that which weighed with Dr. Dudfield and the Medical Officers of Health, and which was also in the mind of the member of the Royal Commission in the above quotation. But in Dr. Bridge's evidence before the Commission, nearly a year later than the date of his Report, he puts the case less decidedly in these words: "I have stated in my Report that in the City of London Workhouse . . . . very few cases of small-pox have occurred." Subsequently, Dr. Aveling, the Medical Officer of the Workhouse, put the exact figures before the Commission (Q. 5037 and 5059-60). He stated that 17 cases had occurred in the eleven years ending December 31, 1881, and that certainly 12, and possibly 15, of these contracted the disease within the institution. The number of inmates is given as 450. Next, the facts as to vaccination require careful attention. In the decade there were three epidemics, the first being by far the worst. The second began about the beginning of the summer of 1876, and may be said to have extended to the end of the summer of 1879. It caused about 3,600 deaths in London. Some 650 of these occurred previous to the end of 1876, and the remainder (approaching 3,000) after that date. Now Dr. Aveling states (Q. 5053) that in the workhouse "re-vaccination was begun properly at the end of 1876, so that these eleven years are divided into two series of six years when re-vaccination was not properly enforced, and a subsequent period of five years when it was tolerably enforced." As to the second epidemic, therefore, we see that less than one-fifth of it had passed before general re-vaccination was instituted. And it is to be particularly noted that of the total 17 cases, 13 occurred in the period ending 1876. In the various streets within a quarter-mile radius of the hospital, the percentage of the population attacked in the ten years 1871-80 ranged from 4 per cent. to 25 per cent., the average being 9 per cent. (*a*) In the workhouse, on the other hand, only some 3 per cent. were attacked. The difference is certainly considerable. But the fact that the cases in the workhouse practically stopped after 1876, when re-vaccination became part of the administrative system, goes far to account for the low attack rate calculated over the whole eleven years. Whether, in addition, anything is to be attributed to the age-distribution of the workhouse inmates, or to previous small-pox, or to the well-regulated conditions as to ventilation, cleanliness, &c., under which they were compelled to live, are questions as to which I have no information. But, on the hypothesis of atmospheric diffusion, it seems likely that people who are mainly kept within doors will be less exposed to infection than persons who walk abroad in the special area without restriction of any kind. In regard, however, to the whole comparison, it is to be borne in mind that the theory of aerial convection does not exclude that of personal communication; and in addition to the influence of re-vaccination, some part of the difference above indicated may well be due to excess of personal communication outside of the institution as compared with the amount inside. Indeed, it is interesting to notice how this very theory comes in with regard to these workhouse cases. The general thesis was that the absence of small-pox was due to the absence of personal communication, and that in particular this absence of personal communication was characteristic of workhouses rather than Poor-law hospitals. But when attention was fastened on the fact that not one, but 12 or 15 cases *had* occurred within the workhouse, then at once it was adduced in explanation that "the visiting had only been stopped at one place one time, and that for a very short time. Visitors came once a month."

In Hackney Workhouse and Infirmary, which was about a quarter of a mile from the hospital, and had in the eleven years 1870-81 an average of 643 inmates, the total number of small-pox cases originating within it amounted to about 20—again about 3 per cent. It was the custom here to vaccinate very early all children born in the institution, and to offer re-vaccination to all the inmates, but a good many refused it. The facts, therefore, are not unlike those relating to the City of London Workhouse. As to the other institutions mentioned, their officials were not called on for evidence, so that detailed examination of the figures cannot be made.

In going over this part of the evidence in the Royal Commission's Report, I made a note to this effect: Were there no other equal populations, not institutional (and, therefore, with no check or personal communication), within the special area which equally escaped? And near the end of my reading I found attention called to the fact that within a quarter of a mile of Fulham Hospital, within the north-west segment of the circle, there were 121 houses which had entirely escaped from 25th May to the middle of September, though 153 admissions into the hospital had taken place during that time. Here, then, was a place which, as regards administrative effort within it to prevent personal communication, was at the opposite pole from the workhouses, but which yet had not a single cases of small-pox during these months. The evidence, however, was adduced, not to throw doubt on the power of personal communication, but on that of the rival theory of aerial convection. But surely the facts are as applicable to the one theory as to the other.

On the whole, I do not think that this evidence regarding these institutions can be looked on as at all sufficient to counterbalance the evidence on the other side.

The practical conclusion of this whole question may be said to have already been arrived at. Small-pox hospitals are not now erected in the midst of towns, and those already in existence are being more and more sparingly used. Indeed, where the power of aerial convection is still doubted, it seems to be assumed that the prevention of personal communication is impracticable, and that accidents incident to the system of hospital treatment of small-pox within populous districts must be accepted as inevitable, so that the only remedy under the one theory, as under the other, is the removal of such institutions to a distance from populous places.

Summing up the evidence, so far as it is possible to sum up on a subject as to which so much is still to be learned, we seem to reach the general conclusion that, as a result of the simultaneous action of cases in influences favourable to the spread of infection, the contagion of small-pox may be conveyed atmospherically to a distance much greater than had been usually admitted, a distance measurable by quarters of miles. In endeavouring to summarise the agencies which have to do with this result, it is necessary to bear in mind that other unknown agencies may also be involved, and that sometimes the joint action of all the known agencies may not be necessary, special activity of some, perhaps, atoning for relative deficiency or absence, and *vice versâ*, of others. Keeping this in view, the factors whose coincident operation can produce the result in question may be subdivided as having to do with: 1, the contagium; 2, the atmosphere; and 3, the population.

1. There must apparently be intensity of virus depending on (*a*) the period of the epidemic, a rising epidemic being important; (*b*) concentration of acute cases as centres of infection; (*c*) possible minor waves of epidemicity referring to particular days or weeks, these waves constituting floodtides of infectivity.

2. (*a*) A foggy condition of atmosphere or light winds appear to be of consequence, as observed both by Waterhouse and Power; (*b*) possibly *only* the atmosphere of towns or cities may possess the necessary carrying power. No good evidence has yet been adduced of such occurrences in connection with hospitals situated in rural districts; but no doubt, the failure here may be as much owing to want of population as to atmospheric condition.

3. Bearing in mind the conclusions arrived at by Dr. Whitelegge in his Milroy Lectures, it may well be the

---

(*a*) See Table, p. 48, *Roy. Com. Report.*

case that part of the influence of a rising epidemic is due to the existence in any special area of a greater or less number of persons specially susceptible to small-pox, and easily infected by its first active onset. The supply of such persons would be rapidly diminished or exhausted, and would not be renewed in the course of any single epidemic.

◆

Selected Prescriptions and Therapeutic Notes.

62.—Application for Chronic Pharyngitis:—

℞ Iodin, gr. vj ;
Pot. iodidi, gr. xij ;
Mentholis, ʒj ;
Glycerini, ad. ℥j ;

M. Apply with a camel-hair brush twice or thrice daily.

63.—Useful in Bronchitic Asthma:—

℞ Pot. iodidi, ʒij ;
Ammon. carb., ʒj ;
Tinct. lobeliæ æth, ʒiv ;
Sp. chloroformi, ʒiv ;
Vin. ipecac., ʒj ;
Infus. senegæ, ad ℥vj.

M. A tablespoonful in a wineglassful of water every four hours.
—*Pharmacopœia of the Edinburgh Royal Infirmary.*

64.—Incontinence of Urine:—

Tincture of Belladonna } ʒij ;
„ „ cubebs, }
„ „ nux vomica, } ʒj ;
„ „ rhus. aromatica, }
„ „ cascarilla ʒij.

Twelve drops at bedtime, for a child from 7 to 10 years. —*From our French Correspondent.*

65.—The Removal of Warts:—

℞ Hydrarg. bichlor, gr. v ;
Acid salicyl, ʒj ;
Collodion, ℥j. M.

This is applied every day, the upper crust of the previous application being removed before a fresh one is made. Usually after four applications the wart becomes so softened that gentle friction will remove it painlessly. If a further dressing is required, a 5 per cent. salicylic-lanolin ointment is all that is necessary. —R. B. Morrison.

66.—Ozæna.—Dr. Stein obtains in ozæna most remarkable results from painting the nasal fossæ with a solution of trichloracetic acid. The painting is done by means of a piece of cotton wool steeped in the solution (1—10 per cent.) and fixed on the point of a flexible wire. The operation is done three times daily for the first few days, and then once a day. The strength of the solution is gradually increased.—*From our French Correspondent.*

67.—Asthma.—The following will be found most useful in this distressing complaint:—

Chloral, } ʒss ;
Iodide of potassium, }
Syrup of oranges, ʒvj ;
Water, ℥vj.

Two to five tablespoonfuls a day.—*Our French Correspondent*

The post of Medical Officer of the Tower of London, which can only be held by retired pay officers, is vacant by the death of Brigade-Surgeon J. Watson, late Army Medical Staff, at the age of 57 years.

Clinical Records.

SHEFFIELD PUBLIC HOSPITAL.

Case of Fracture of the Larynx—Tracheotomy—Death.

Under the care of Mr. Hy. Lockwood,
Surgeon to the Hospital.

The patient, a man, æt. 46, was admitted into the hospital under me on Jan. 4th. He walked up to the hospital and said that a loose end of his necktie had caught some belting and swung him round by the neck. On admittance there was a red line round his neck and considerable bruising. He complained of difficulty in breathing and inability to swallow without very great pain. He had spit up a considerable quantity of blood. On examination the thyroid cartilage was found displaced round to the left, and with a depressed fracture of the right area of the thyroid bone. He was fed during the night on peptonised enemata, and had a bad night, with several attacks of dyspnœa. On Friday, Jan. 5th, in the evening tracheotomy was performed after consultation with my colleagues. There was manifest relief immediately after the operation. The opening in the trachea was enlarged upwards and with the finger an effort made to replace the depressed piece of bone and with apparent success. He slept well the night succeeding the operation, and on Saturday, his temperature, although rather high, he seemed better, the discharge through the opening smelt purulent. I tried to feed him through the mouth but the fluid (milk) came through the tracheotomy tube, suggesting rupture of œsophagus. The night of Jan. 6th was on the whole good, but his temperature rose to 103° during the night, but was coming down in the morning.

Jan 7th.—Condition much the same, complained of no pain. An effort was made without success to pass an india-rubber stomach tube, but we were more successful with a No. 12 elastic catheter, through which about a pint of milk with an ounce of brandy was injected into the stomach. None came back and this was continued during the rest of his life. On passing the tube into his stomach he seemed to suffer no inconvenience, and he seemed not to feel any irritation from the presence of the tube at the back of his pharynx, and there seemed an entire loss of sensibility of those parts.

The last time he was fed was Saturday night, Jan. 6th, about 12 a.m., and he seemed fairly comfortable, but sank somewhat suddenly about 4 a.m. and died.

Dr. Sweeton thought the immediate cause of death might be possibly attributed to crushing of the vagus nerve.

To Dr. A. Hall I am much indebted for the following notes on the morbid specimen:—

"On opening the œsophagus and larynx from behind it is seen that the epiglottis has been transversely severed from the rest of the larynx except at the base in front. On the left side the thyro-epiglottidean fold has been completely torn through from behind forwards, whilst on the right side a small portion of the upper border of the thyroid cartilage fractured transversely has been carried up with the thyro-epiglottidean membrane, the superior cornu on this side is broken off and remains attached to the thyro-hyoid membrane and wall of the pharynx. All the parts around the upper larynx are sloughing and putrid. This separation of the epiglottis and the folds from the rest of the larynx has left a large transverse gap above the larynx, which consists only of the muscular walls and thyro-hyoid membrane. The thyroid cartilage is excessively mutilated. Besides the portions above mentioned as being torn off and carried upwards with the right thyro-epiglottidean fold, &c., the thyroid cartilage is fractured vertically down the middle. The left ala is driven backwards in contact with the back of the cricoid ring whilst the right is curled up. The cricoid cartilage is fractured across the front. The compression of the thyroid cartilage has made the opening in the larynx exceedingly narrow and completely disorganised the vocal cords, especially the left. The tearing away of the attachments of the epiglottis must also have entirely prevented the epiglottis performing its function of covering the larynx. The wound made in the operation is immediately below the ring of the cricoid. With such a condition the mechanism of deglutition must have been quite disorganised and probably sensation in the upper larynx lost from injury to the superior laryngeal nerve, and it seems likely that any liquid the patient tried to swallow found its way merely into the pharynx and larynx and never reached the stomach at all, hence a fit of coughing brought it back into the wound. The discharge of blood and matter from the putrid surface of the upper larynx must also have considerably contributed to the condition of the lungs, which, although showing no pneumonia were very much enlarged How far the injury to the tragi in the neck at the time of the accident affected the heart's action or condition of the lung is worth consideration, but impossible to prove.

◆

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held February 8th.

The President, Professor Thomas Savage, in the Chair.

SPECIMENS.

Mr. Mayo Robson (Leeds) showed: 1. A "Multilocular Ovarian Cyst," to which was attached a tube with thick walls, which from its attachment and position in the pelvis was believed to be the right horn of a bicornuate uterus. The patient, æt. 34, was the mother of three children, youngest 9 years old. She had had pelvic discomfort and pain for nine years; and had noticed the tumour since five years, during this time the pelvic distress had increased. Since June, 1893, she had lost flesh and strength, and had been unable to work. On examination, a tumour was found, giving dulness on percussion up to the umbilicus; by binaural examination the mass was found to the right of the uterus and moving with it. Operation January 13th, when the parts shown were removed. On the left side was a normal ovary. Owing to torn adhesions, drainage was used. Recovery. 2. Two cysts attached to the right ovary, one at its upper border by a long pedicle, the other at its lower border by a short thin pedicle. They contained respectively one and two pints of dark fluid. Three weeks before operation the patient had a violent attack of peritonitis, due to twisting of the longer pedicle. The left ovary was normal and was left. Drainage for two days. Recovery. 3. "Myoma of the uterus," removed by the intraperitoneal method described by the author in the *Brit. Med. Jour.* three weeks ago. The patient was profoundly anæmic from frequent and profuse metrorrhagia extending over seven years. As the ovaries were situated deeply in the pelvis behind the tumour, and could only be exposed by bringing the uterus forward through the abdominal incision, hysterectomy was thought to be preferable to oophorectomy. No drainage was required. Recovery.

The President observed that the second specimen seemed, from a short examination, to be a papillomatous cyst of a variety which frequently affected both sides and gave rise to the presence of fluid in the abdomen.

Dr. Leith Napier agreed that both cysts were papillomatous, one wholly, and one partly. The second cyst had such thin walls as to suggest a parovarian origin. The first specimen was of great interest, and he hoped Mr. Mayo Robson would be able to give them a later history.

Mr. Taylor asked if there were a trace of Fallopian tube at the end of the supposed cornu?

Mr. Reeves commented on the interesting nature of the cysts shown. With reference to the third specimen he was glad Mr. Mayo Robson had adopted that method of hysterectomy, as it was simple and comparatively easy. The indication for the operation was hæmorrhage; in such cases a fibroid growth or polypus was often found in the cavity of the uterus. It would therefore be interesting to have the specimen further dissected.

Dr. Bantock, in speaking of the first specimen, said he had not met with a case like it, in the course of a tolerably large experience. But he thought the second specimen was of even greater interest; it seemed to him to be an exaggerated condition of the growth described as Rokitansky's tumour, which he believed to be malignant. This view received support from the fact that both sides were papillomatous. But in this case, instead of numerous cysts arranged in grape-like fashion, there were only two. He had once operated on a young lady with numerous cysts springing from the ovary. Some of these had ruptured before operation. She recovered from the operation and went home, but in two months she died of recurrence. He congratulated Mr. Mayo Robson on the success of his intra-peritoneal operation. But he did not understand Mr. Robson to advocate it in all cases. He assumed that in this case the conditions were favourable for the intra-peritoneal method; but statistics proved that the extra-peritoneal gave the best results. He had been rather amused to see that a surgeon at a General Hospital lately quoted Schrœder's operation-statistics with approval; in reality those results were bad, but they had been improved on since. They were not such as would be now appealed to by an operator who was *au courant*. In a recent case of small pedunculated fibroid of the uterus attached to the cornu, the patient was a young married lady, whose ovaries were quite healthy, so that there was a possibility of her becoming pregnant. He, therefore, decided to depart from his usual custom, and perform an intra-peritoneal operation. It was difficult, and there was much hæmorrhage, so that he had to use a drainage tube. This confirmed his opinion of the relative value of the two methods. Of operations performed on the extra-peritoneal principle, he had 19 cases of pedunculated fibroids with no deaths, whilst of his last 43 supra-pubic hyterectomies, he had lost only 3.

Mr. Bowreman Jessett referred to a plan he had lately advocated of total extirpation by abdominal section; the peritoneal flaps that were left were turned down into the vagina, and formed an effectual valve preventing the entry of harmful matters into the peritoneal cavity. Drainage could be used or not as desired. For a small myoma, this seemed to him a better method than cutting the uterus across. An abdominal hysterectomy was by this means practically converted into a vaginal hysterectomy.

Mr. Mayo Robson, in reply, explained his method of lacing the peritoneum across the stump, the uterus having been amputated by flaps at the level of the os internum. He agreed with Dr. Bantock that this was an eclectic method. Mr. Robson acknowledged in a graceful manner his indebtedness to Dr. Bantock for such good results as he had had; he had performed fifteen hysterectomies by the extra-peritoneal method, and had had no deaths. It was chiefly to avoid the long convalescence that this method entailed that he used the intra-peritoneal method; but on other grounds also he preferred it. He would be glad to have the specimens further examined. With regard to the second, the operation was six weeks ago, and he had not seen the patient since; the wound healed by first intention. He was much interested by Dr. Bantock's remarks about his case; the prognosis, as Dr. Bantock had pointed out, was, however, modified by the fact that in his own case there was no rupture of the cysts before operation.

Dr. Heywood Smith showed an "Ovarian Cyst" with a uterus removed by the method of total extirpation by abdominal section. Patient, æt. 48, widow 3½ years, had borne no children during her married life of twenty years. Catamenia regular, had become freer last seven years. Complete procidentia at intervals since March, 1890. She had had right inguinal pain for fifteen months. On examination, abdominal palpation showed a soft tumour on the left side of the uterus. By vagina, the cervix was very soft and flabby, projecting two inches beyond the vulva. The cavity of the uterus was 4½ inches long, and on the right side of the body there was a fibroid. *Operation.*—The vagina was first packed with sal-alembroth gauze. The abdominal incision was six inches long, and through this the uterus and its tumour were drawn out. The right ovary was the size of the fist. Each broad ligament was secured in three portions, and the uterus was separated completely by scissors and fingers. The separation of the bladder caused a little difficulty. There was very little bleeding; the peritoneum was sutured with a continuous Bishop's stitch. The edges of the abdominal wound were brought together in three layers. Finally, the vagina was packed with iodoform gauze. The operation lasted one hour and forty minutes. The patient died of peritonitis on the third day. The uterus when cut open contained three mucous polypi and a fibroid. The wall of the ovary was very thick; there were two main cysts, one containing a clear fluid, and the other a blood-stained jelly. He thought that perhaps vaginal hysterectomy would have given a better result.

Dr. **Schacht** who was present at the operation, said that he had been struck by the apparent ease of the operation, which was the first of its kind he had seen. The chief time and difficulty were concerned with the separation of the long cervix. At the close, the whole thing looked very complete and satisfactory, and the operation seemed to him a very feasible one.

The **President** then delivered his Inaugural Address.

Dr. **Robert Barnes** moved a hearty vote of thanks to the President for his interesting address, and asked him, on behalf of the Society, to allow it to be printed in the Transactions. After referring to the pleasure it had given him to be once more among them, he said he was glad to hear the reverent tone in which the President spoke of the attitude of freedom in gynæcology. There was in the Provinces an amount of freedom which was denied to them in London. The want of it had been a difficulty to him in his own career, and he had been obliged to move from place to place in his pursuit of it. Gynæcology had thrown much light on modern surgery; and their society was, in fact, a surgical as well as a gynæcological society. Their work derived exactitude from the fact that the organs with which they had to deal were all under the direct control of the eye and hand. The address would be a stimulus to further effort wherever the journal was circulated.

Dr. **Bantock** seconded the motion, and spoke of the necessity there was for gynæcology to be dissociated from obstetrics, and taught as a separate branch of medicine. If, he said, he were on the staff of a general hospital, he would do all he could to advocate this measure; as it was, being on the staff of a special hospital, he had no means of doing so.

The **President** briefly returned thanks to the Fellows for their kind vote of thanks and for the honour they had conferred on him by placing him in the presidential chair.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Anatomy.

Meeting held Friday, January 26th.

The President, Dr. **Alex. Fraser**, in the Chair.

Exhibits.

The President exhibited enlarged photographs of human and other vertebrate embryos. The human embryos ranged from the third week down to half term. They also embraced sections of birds from the first day down to the breaking of the shell. Some of the photographs exhibited included those of rabbits, sheep, pigs, calves, rats, &c.

Dr. **R. H. Woods** exhibited specimens of enlarged turbinated bones causing obstruction. The first specimen was taken from the left nostril of a woman, æt. 45. He took away the anterior part of the bone and found it to consist of a tumour, which was hollow and which came away on pulling it with an artery forceps. The second specimen was a dissecting room one, and the anterior end of the middle turbinated bone was enlarged. On making a small opening into it, it was found to be hollow, and it evidently must have caused some slight obstruction during life.

Mr. **F. A. Nixon** said the specimens were of interest, especially as they showed the difficulties there is in sometimes recognising a nasal polypus. He also saw a case in which the extreme obliquity of the septum simulated a polypus. The disease attacked not only the inferior turbinated bone but the middle as well.

Sir **William Stokes** having taken the chair,

The **President** delivered an address on the position of anatomy in general, and certain problems in connection with the evolution of the central nervous system in particular. There was also a lime-light demonstration illustrating anatomy from the morphological side (macroscopic, minute, and developmental).

Sir **W. Stokes** said they were aware that it was not customary in the Academy to discuss any points that might be raised in an inaugural address. The subject was one of special interest; still he thought it well not to deviate from their usual custom on the present occasion. But there was one thing that they could do, and that was to pass a special vote of thanks to the President for the learned, lucid, and original paper which they had just heard.

The vote was carried with acclamation, and the President returned his thanks to the members.

CASE OF SINGLE KIDNEY.

Dr. **H. C. Tweedy** exhibited a case of "single kidney" taken from the body of a woman, æt. 30. The left kidney was greatly enlarged. The left renal vessels were normally placed, but were also larger than usual. The ureter was much wider and also apparently thicker than in the natural condition. No trace of kidney could be found on right side, and careful dissection revealed no artery or vein, large or small, corresponding to the vessels supplying the existing kidney. No ureter was found on the right side. Dr. Tweedy drew attention to the rarity of this condition, only about 100 cases being on record, the proportion of females to males being about 1 to 4, and quoted a statement recently made by Dr. MacDonald Brown, that out of 12,000 autopsies made in the various London hospitals, only three cases of "single kidney" were met with. The case was further worthy of notice in that no congenital defects were discoverable in other organs. Nor were there any indications during life that the condition existed. The patient died of cirrhosis of the liver, followed by peritonitis, and the cause of death was in no way connected with the absence of the right kidney.

Professor **Cunningham** thought that the members of the Anatomical Section should feel greatly indebted to Dr. Tweedy for bringing this specimen before them. He had very little doubt that it was a *bona fide* absence of the kidney. This was an extremely rare condition, and on that account the interest in it was considerably heightened.

Professor **Birmingham** said that a point of special interest in the specimen was the peculiar condition of one renal vein, which for a little part of its course was divided into two and united again.

Professor **Purser** inquired whether the broad ligament of the uterus was examined on that side, or whether the remains of the Wolffian bodies were to be found.

Professor **Fraser** said that in reference to the aperture in the renal vein, he remembered somewhat similar arrangement of veins in the pelvis which formed a *rete mirabile*.

Dr. **Tweedy** explained that no special examination was made of the broad ligaments of the uterus, because at the time their attention was directed in looking for a special pathological condition.

Professor **Fraser** next made a communication on

THE LOBUS OLFACTORIUS IMPAR OF BIRDS AND MAMMALS.

He said it was well marked in the human brain, or at least the region that is taken for it. It was a hollow in the human brain which lies above the anterior commissure and between the two pillars of the fornix. It was named the recessus triangularis by Schwalbe, of Strasburg. He had long been familiar with the condition in embryos, but it was only lately that it had been brought into notice by Von Kupfer, of Munich. It was of great importance although of no size, and he had seen it in the whole of the vertebrate series.

Professor **Symington** said that the olfactory part of the brain has lately attracted great interest. He thought, however, they needed some further proof that the part described by Prof. Fraser was in communication with the olfactory bulbs. In the adult brain it appears to have a slight communication with the olfactory bulbs, but he would like very much to know if Prof. Fraser could show them the degree of communication between this recess and the olfactory bulbs, either in man or the higher mammals. He did not quite grasp this relation to the olfactory bulbs, and he did not yet quite realise the grounds upon which Prof. Fraser had come to this conclusion.

Professor Haddon explained that in some lower forms the only opening to the alimentary canal was through the anterior part of the nervous system, and this might account for the little recess. Prof. Fraser had referred to the condition in the lamprey, but that species was rather a group in itself and off the main line, and little could be deduced from its condition. In conclusion, he failed to see what the neural canal had to do with the olfactory organ.

Professor Fraser said he did not think it was a greater jump to conclude that the little recessus triangularis was a median olfactory lobe than the conclusion about the median eye. There was a median thickening of the epiblasts corresponding to the little projections from the median aspect of the brain, just as there was a lateral thickening of the epiblasts corresponding to the lateral nostrils. In his opinion it was a very erroneous and unscientific way to judge of the importance of a structure from the adult condition in which it was found.

The Section then adjourned.

◆

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, February 7th, 1894.

The President, Dr. G. E. Herman, in the Chair.

A CASE OF ECTOPIC RUPTURED EXTRA-UTERINE GESTATION.

Dr. Duncan: I was called the other day to a patient who, baving missed a menstrual period, had suddenly collapsed with symptoms pointing to severe internal hæmorrhage. The practitioner in attendance has diagnosed ruptured extra-uterine gestation, and when I arrived I found her blanched, with a feeble pulse, and so collapsed that I thought it better to obtain the apparatus for transfusion before proceding to operate. I then opened the abdomen in the middle line, and found it filled with blood and clots with unequivocal signs of a rupture of the left Fallopian tube. The patient's pulse improved so much under ether that I did not think it necessary or desirable to employ transfusion. She made a good recovery. Had transfusion been resorted to in this case, the patient's recovery would doubtless have been ascribed to its influence. He did not flush or drain.

Dr. Horrocks observed that, although the patient in this case recovered without transfusion, the literature of the subject furnished a number of instances in which, though the patient rallied for the time being, death had ensued within a comparatively short time with indications of cardiac failure. He was of opinion that many of these cases would have recovered had transfusion been employed, and he urged that it was better to act on the general principle that transfusion was capable of rendering very great service after copious hæmorrhage than to accept this one observation as a reason for discarding it. He was of opinion that transfusion ought always to be had recourse to when there was marked collapse.

Dr. Braxton Hicks pointed out that there was a great difference in the physiological effects of transfusion according to circumstances. In labour, for instance, where a further copious loss of blood might at any moment take place, and its employment in surgical cases such as that brought to their notice by the author, cases, in fact, in which the possibility of further hæmorrhage has been provided against.

Dr. Boxall observed that one advantage of flushing in these cases was that the absorption of a comparatively large quantity of warm fluid by the peritoneum produced restorative effects after hæmorrhage, equivalent to intravenous transfusion.

Dr. Dakin said it would not be rational to have recourse to transfusion unless and until further hæmorrhage has not been effectually guarded against. In post-partum hæmorrhage, for example, the rise in the blood pressure and the general stimulating effects of the injection would be calculated to increase the subsequent liability to hæmorrhage.

Dr. Spencer declined to admit that the diagnosis of ectopic gestation was as easy as the author would lead them to infer. Martin, of Berlin, with an experience of 56 cases, had asserted that the diagnosis was rather a matter of probability than of certainty. He had not gathered from the author's description of the case that it was for certain a case of ruptured tubal gestation, and not an ordinary case of hæmatosalpinx. That very morning he had operated on a patient thought to be in the sixth month of pregnancy. There was a tumour, evidently the uterus, in the middle line of the abdomen. This was the size of a 3½ months' pregnancy. It was freely movable, and quite distinct from the tumour, a very unusual circumstance in a case of extra-uterine pregnancy. Behind the uterus was a large cyst, its dimensions being those of a six months gestation, from which he had removed a six months fœtus. He was by no means certain that the patient had not an intra-uterine pregnancy. It was very difficult indeed to be sure of the exact nature of the case beforehand, considering the large size of the uterus and its extreme and independent mobility.

Dr. Duncan, in reply, observed that if a patient were in such a condition as for her recovery to depend upon the absorption of fluid by the peritoneum, transfusion ought to be performed, for it was a more certain and reliable means of restoring the balance of the circulation. He would have had recourse to transfusion in this case had the patient's condition not improved so materially under ether. He would never have recourse to transfusion until he had effectually guarded against the possibility of further hæmorrhage. He did not affirm absolutely that it was a case of extra-uterine gestation, but he thought that symptoms of severe internal hæmorrhage in a woman who had seen nothing for five weeks warranted that diagnosis, the examination of the specimen would clear the question. He had preferred to defer the dissection until they had had an opportunity of seeing it.

Annual Meeting.

The annual report was read showing that the society was in a satisfactory financial condition, the membership having increased during the past twelve months to an extent unequalled for many years.

According to the report of the Board of Examiners of Midwives there were 339 candidates for the diploma of the society during the year 1893. Of this number 296 passed and 40 failed. Between the years 1872 and 1892 the total number of candidates had been 1,677, of which number 1,376 passed. During that period three midwives have been removed from the list for misconduct.

The President then delivered the Annual Address. He reviewed the work done by the Society during the preceding twelve months, much of which, he pointed out, was work of the first order. He alluded in terms of special commendation to the laborious investigations of Dr. Boxall on the incidence of puerperal fever, and of Dr. Giles on lochial discharges. He concluded by giving concise biographies of the deceased Fellows.

After the usual votes of thanks the Society adjourned.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Thursday, February 1st, 1894.

The President, Mr. Richard Favell, M.R.C.S., in the Chair.

SPECIMENS.

Mr. Arthur Jackson exhibited a "Naso-Pharyngeal Polypus." A detailed account of the case will be found in our issue for February 14th, under the heading of "Clinical Records."

Mr. Snell showed a child with "Congenital Subconjunctival Lipoma."

Mr. Makeig Jones related a case of a woman, æt. 35, who died of "exhaustion from vomiting" when nearly at the end of pregnancy, ten months after developing symptoms of cerebral tumours. The symptoms were severe pain over right forehead coming on in paroxysms, with slight ptosis and external strabismus of right eye, vomiting and double of the neuritis. On post-mortem, a tumour about the size of a hen's egg was found in the right frontal convolutions, growing downwards from the dura-mater. Dr. Buxton showed some beautiful sections of the tumour, showing it to be an endothelioma.

Mr. Makeig Jones also showed a man, æt. 40, who came to him eighteen weeks after having had a "dislocation of the head of the right humerus" (which was immediately reduced under chloroform), suffering from inability to raise the arm. There was atrophy of the infra- and supraspinata, deltoid, and trapezius, and contraction of the teres major, but the man was recovering under galvanism. It answered to Charcot's amyotrophic articular paralysis of traumatic origin.

CASE OF ATAXIC PARAPLEGIA.

Dr. **Somerville**, for Dr. Hunt, read the notes of a case of a man, æt. 44, who, during the last 8 years had suffered from weakness of the right arm and both legs, and who for some years previously had been subject to paralytic symptoms of a temporary nature. The patient was shown to the Society, and the points drawn attention to were the myotatic irritability of the muscles of the affected limb, the exaggerated knee-jerk of the right side, the action of the flexors of the right hand overcoming that of the extensors when the hand had been fully extended for about a minute, and the tendency to spasmodic contractions which were sometimes induced by attempting certain movements, and the inability to stand with the eyes shut. It was also pointed out that the patient had never suffered from pains of the body or limbs, and that cutaneous sensibility was normal. The bearing of these symptoms was discussed, and the opinion was expressed that it was a case of ataxic paraplegia.

A CASE OF SCARLATINA WITH UNUSUALLY PROTRACTED HIGH TEMPERATURE, AND WITHOUT LOCAL COMPLICATIONS.

Mr. E. W. **Clarke** showed the temperature chart of a case of scarlatina in which, without the presence throughout of any complications, the temperature which had fallen on the fading of the rash to 100·8°, rose again suddenly to 102·6°, and remained elevated for ten days with an evening rise each day, about 6·30 p.m., to 102·6 or 102·8°. On the 7th day of the renewed rise, a dose of antipyrin was given to anticipate the coming rise, and a little later a cold pack, after which the temperature became normal, never rising again beyond 101°. and subsequently resuming its normal curve on the 10th day. Throughout desquamation proceeded, and beyond an unimportant enlargement of the cervical lymphatic glands, there were no complications whatever. The literature of this condition was discussed, and in particular, the recent paper of Bouvent. The cause of the secondary rise of temperature was considered to be the action of atoxin, either scarlatinal as the result of secondary infection.

◆

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Tuesday, February 6th.

The President, Mr. John Appleyard, M.B., F.R.C.S., in the Chair.

AFTER TREATMENT OF SEVERE SURGICAL CASES.

Mr. **Horrocks** pointed out that surgery nowadays was greatly a matter of details. After severe operations treatment is chiefly directed towards relieving shock and relieving the sickness after anæsthesia. Owing to anæsthetics the effects of shock, which are most noticeable in the very old or the very young, are too generally neglected; they may be best met by brandy or opium by the mouth as soon as the chloroform sickness has passed off, by warmth, and if necessary, by inhalation of oxygen; in cases with hæmorrhage the slow intravenous injection of several pints of a sterilised, one in a thousand, saline solution, the injection of hot water *per rectum* and inhalation of oxygen are most useful. Sickness is the great trouble after anæsthetics, when it has been present before operation it is generally serious, washing out the stomach before the patient recovers from the anæsthetic generally gives great relief. When ether has been used, bronchial irritation is common, and is best relieved by inhalations of steam with tincture of benzoin. Abstention from food for many hours is generally recommended, but the old and the very young do with small quantities of brandy or beef tea at short intervals within a few hours of operation. In many operations about upper part of abdomen food has been given *per rectum*, with good effect within ten hours, in pelvic cases mouth feeding is best; nutrient suppositories may lie unabsorbed for hours after operation. Purgatives are probably useful in stages of peritoneal effusion due to sepsis, harmful in plastic peritonitis, and useless in advanced cases, or general septic peritonitis.

INTRACRANIAL DISEASE SECONDARY TO EAR DISEASE.

Dr. **Adolf Bronner** read a paper on this subject. He remarked that in very many cases this condition is not diagnosed, especially in children, fits, convulsions, or meningitis being recorded as the cause of death, the aural troubles being passed over. The mastoid cells, attic and tympanum are all very close to the cranial cavity, the tegmen is often very thin, the size of the cavities varies much, so that every chronic ear case is dangerous. In mastoid cases, if common methods fail to benefit, one must open the mastoid cells. In children where the full bony development is not completed the petro-squamous fissure connects middle ear and cranial cavity, and we often have meningitis or other cranial symptoms without very evident ear disease, which has to be carefully looked for. Thrombosis is common in adults but rare in children, infective thrombus causes pigmentation and erosion of the bone, general systemic infection usually shows itself first in the lungs. Differential diagnosis is easy in uncomplicated cases, but where thrombosis, cerebral abscess, and meningitis are all present, the conditions may be very difficult to analyse. Seventy-two cases were operated on recently (many not being undertaken because obviously dying), but some apparently hopeless cases did well. Dr. Bronner considered that the future outlook for surgery in this field is good, but in most cases operations would never be required if aural discharge had not at some time been neglected.

SPECIMENS.

Dr. **Major**: Brain from an imbecile, one-half being very small.

Dr. **Wood**: Cancer of the bladder with extreme anæmia and retinal hæmorrhages.

Dr. A. **Bronner**: Periovarian cyst communicating with sigmoid flexure.

◆

THE HUNTERIAN SOCIETY.

Meeting held Wednesday, Jan. 24th.

The President, Mr. F. Gordon Brown, in the Chair.

Case of Atheroma.—The **President** showed a policeman with a systolic aortic bruit and other signs of atheroma, who two years before had been injured in the left foot. The left dorsalis pedis artery was now aneurysmal, and pulsation had been cured by recent ligature of the anterior tibial.

Case of Graves' Disease.—Dr. **Hingston Fox** showed a case of Graves' Disease in Childhood. William N., a boy, æt. 12, had been brought to St. Luke's Dispensary occasionally since infancy, suffering from minor ailments—eczema, enlarged glands, bronchial catarrh, scarlatina, &c. Six years ago nervous twitches and over-acting heart were noted as present. He was one of three children, one being still-born, and the third died of convulsions. He had been attending for 16 months past; at first only impaired nutrition with dyspepsia were observed; tremor of hands had now been noticed for twelve months, proptosis for eight months, with irritable knee-jerks. Diarrhœa became troublesome in the summer, and proved obstinate, especially from 4 to 7 a.m. daily, being at length partly controlled by enemata of tannic acid and opium internally. Rapidity of heart's action had only come on this winter, the pulse rate rising to 115, seldom down to 90. He had been treated for six weeks past with a mixture of pot. iodid. and pot. bromid., with iron and belladona, of the latter ♏ 1½ of the liquid extract (equivalent to ♏ xxi of the tincture) three times a day, besides cod-liver oil. The diarrhœa had ceased, and he was altogether better, so that beyond the proptosis and slight tremors there were no very apparent morbid signs. No thyroid enlargement could be made out, but the other three cardinal symptoms of the disease were present; it was unusual to see it at so early an age.

Case of Aneurysm.—Dr. **Dawson** showed a female, æt. 56, with aneurysm of the right innominate artery, the size of an egg, and of five years duration. Her symptoms were occasional pains in the shoulder and precordial region, sleeplessness, and dyspnœa, and palpitation on exertion. She had a diastolic bruit at the apex, and a double bruit heard on the right side of the base. Dr. Dawson considered surgical treatment uncalled for at the present time.

Case of Bronchiectasis.—Dr. **Arnold Chaplin** showed a case of bronchiectasis, treated with creosote inhalations. The patient, a girl of 16, gave the following history:—When a child she had whooping-cough, and since then a paroxysmal cough, coming on in the morning when waking, and often culminating in vomiting. This cough has been attended for the last three years with profuse, horribly foul expectoration, which comes up in gushes and fills the spittoon and renders her a trouble to herself and to those with whom she associates. In addition to this she has severe dyspnœa on exertion, loses flesh, and is troubled with night sweats. On examining the chest there is some slight fulness at the right base, especially behind. The percussion note is impaired almost to dulness below the inferior angle of the scapula. Just below and external to the angle the note is tubular. This impairment passes round to the front below the nipple. On auscultation there are to be heard creakings, crepitations, coarse and bubbling râles, attended with weak bronchial breath sound, and bronchophony, which became intensified after coughing. The patient had been in the City of London Hospital for Diseases of the Chest, under the care of Dr. Thorowgood. Various remedies were tried with a view to diminishing the fœtor of the expectoration, but without success. She was again admitted towards the end of last year, and by the courtesy of Dr. Thorowgood was treated by Dr. Chaplin in a different way. The method of treatment was as follows:—Some coal-tar creosote, which consists principally of pyridine bases, phenates and acridin, together with the other products of the distillation of coal-tar was obtained, and a small chamber fitted up and made as air-tight as possible. Some of this creasote was put in a dish and heated by a spirit lamp until the fumes were given off in great quantity. The patient was then placed in the chamber, and inhaled the fumes with which it was filled for one hour every day. This inhalation produced violent coughing, with the expulsion of much expectoration. After three inhalations the morning paroxysm of coughing was absent, and the expectoration became sweet. The treatment was then discontinued for two days, and the old state of things returned, soon to be removed, however, on the resumption of the treatment. The patient has had 54 inhalations lasting one hour, with the result that the expectoration is much less, and has remained free from odour for a month without any creosote inhalation whatever. This has never happened before for the last three years. The patient states that her breathlessness and cough are but trifling now, and that the night sweating has ceased. It is submitted that this method, in this case at least, has done what other forms of treatment were proved to be incapable of accomplishing, viz., to free the expectoration from that most distressing of all symptoms in bronchiectasis—fœtor.

Dr. F. J. **Smith** showed a case of transposition of the viscera in a boy, æt. 15, who was in good health.

Dr. F. C. **Turner** showed a girl, æt. 12, who presented multiple exostosis of ribs, clavicles, humeri, and tibiæ.

Dr. **Batten** exhibited his new pulse manometer.

◆

CATHOLIC UNIVERSITY MEDICAL SCHOOL MEDICAL AND SCIENTIFIC SOCIETY.

A **meeting** of this Society was held at the Medical School, Cecilia Street, on Monday eveing, Feb. 12th, Dr. A. Roche, Vice-President, in the chair.

Dr. H. **Byrne** showed a case of chronic hydrocephalus in a boy, æt. 9. The boy was quite intelligent, but could not walk well.

Dr. **Shine** exhibited an enormous mucoid adeno-sarcoma of the mammary gland.

Surgeon **McArdle** had noted in these cases the blood appeared during the operation to be very pale, and did not coagulate.

Dr. **McWeeney** showed a case of tricuspid regurgitation with consequent venous congestion of organs. The patient had suffered from a severe burn some years ago, and the cicatrix of an ulcer was found in the duodenum.

Mr. **Halligan** read a paper on

A CASE OF SIMULATED ELEPHANTIASIS.

The girl had been admitted into the Mater Misericordiæ Hospital suffering from scarlatina, when the enlargement of her leg was noticed. It was of four years' duration. There had been no fever, and her blood contained no parasite. Her urine was normal.

The Vice-President, Dr. McWeeney, Dr. Adye Curran, Dr. McArdle, and Mr. Forrest discussed the case.

Dr. **Adye Curran** read a paper on

A CASE OF ATRESIA ANI.

An effort was made to find the rectum by incision from below without result. The parents refused colotomy, and the child died.

Dr. **McArdle** preferred colotomy in the left inguinal region in these cases. He had noticed how well infants bore operations, so they were not too much prolonged.

Dr. **Curran** replied.

Mr. **Howley** read a most interesting paper on

THE THERAPEUTICS OF SUGGESTION.

The **Vice-President** pointed out some of the dangers, both to the mind and free will in some cases. It had been found useless in the Bombay Hospital years ago for surgical operations.

Drs. McWeeney, Coffey, O'Gorman, Curran, and McArdle joined in the discussion.

The Society then adjourned.

Myxœdema.

At the Société des Hôpitaux M. Marie related the case of a woman who was suffering for eight years from myxœdema of a very pronounced form. He treated her by ingestion of raw thyroid gland.

At first the results were *nil*, but a microscopical examination of the gland furnished by the butcher discovered that it was not a thyroid, but a submaxilary gland. The thyroid body was then obtained directly from the slaughter-house, and then the results were entirely different. The first dose (two thyroid bodies) was taken on the evening of the 19th November, and the following day the temperature rose to 100° and remained at that figure several days. At the same time diuresis set in, and the patient began to feel a pricking sensation (*gourmillements*) in the legs. Two days subsequently the pulse stood at 102, and the dose was consequently diminished to one lobe a day. The improvement in the myxœdema was very apparent; the swellings under the eyes had almost disappeared. The following days the patient complained of insomnia, headache, pains in the legs, and great thirst, the pulse rose to 112, and the temperature remained at 100° F. A slight trace of albumen was found in the urine. On account of the intensity of the symptoms the treatment was suppressed entirely for a few days. In the meanwhile the phenomena abated, the pulse fell to 80, and the temperature to 99°. The patient was not yet able to walk about with ease. Three weeks subsequently the treatment was recommenced (one lobe every two days), but after the seventh day the headache and all the other symptoms returned with renewed intensity, and the treatment had to be again suspended. However, on the 11th January two-thirds of a lobe were ordered every *five* days, and in this manner no evil effects were produced.

As to the myxœdema, it had disappeared completely, the body had resumed its normal appearance, and no one would have suspected that the patient had ever suffered from the affection. She weighed (in her clothes) at the beginning 102 kilogrammes, and on the 24th January her weight was 85 kilos, or a decrease of 17.

In a moral point of view, the improvement was not less satisfactory. The state of idiocy and the fearful nightmares the patient suffered from disappeared. Her good spirits returned and she took pleasure in going out frequently, whereas hitherto she had always remained shut up and indifferent to all that was going on around her.

In concluding, M. Marie said that he did not intend insisting on the efficacy of the treatment, for that was an established fact, but on the intensive action of this treatment, and the necessity of proceeding cautiously.

The method of administration which seemed preferable to him was as follows: Take a lobe of fresh thyroid, cut it in small pieces on a soup plate and throw hot soup over it and let the patient immediately drink it. One lobe should be given daily for three or four days, then every two days, and finally every five days.

BERLIN, Feb. 16th.

THE ETIOLOGY OF INFLUENZA.

DR. R. PFEIFFER, who is well-known as the Director of the Scientific Department of the State Institute for Infectious Diseases, has an article on this subject in the *Zeitsch. f. Hyg. u. Infektionskrankh*, Bd. xiii, H. 3. Since the preliminary communication on the exciting cause of the disease made a year ago, the author's studies have been continued, and in the present article he relates his further systematic inquiries into the subject. It is generally known that in the last epidemic the author found a hitherto unknown, well characterised, minute bacillus, and he succeeded in showing its etiological significance in regard to influenza. Attempts at pure cultivation of the bacillus failed except in a few cases, in which sputum or pus from the expectoration were spread on agar, from which small perfectly transparent colonies of bacilli were obtained. The attempt to produce further cultivation from these colonies, however, always failed. The first object of the Professor was therefore to bring those cultivation experiments to a satisfactory close. These only succeeded when human or suitable animal blood was mixed with the nutrient soil. When the influenza is purulent sputa have been spread on blood-agar, it has been easy to procure the colonies, and to continue the cultivation through successive generations, whilst inoculations on to every other nutrient soil have remained sterile. Further investigation showed that the constituent of the blood required by the bacillus was the hæmoglobin of the red blood corpuscles. It was now easy to determine the conditions of existence of the influenza bacillus. They were strictly anaerobic; the extreme limits of temperature for their development were 42 C. and 26 to 27 C. They quickly died off in drinking water, in nutrient soils suited to them they lived about 14 days; they were very susceptible to drying. It might be assumed that they could live in moist sputum about 14 days. A permanent form of the bacillus had not been discovered.

From his investigations the author draws the following practical conclusions: 1. Development of the influenza bacillus in soil or water outside the human body is not possible. 2. The spread of the disease by direct sputum reduced to dust can only take place to a limited extent. 3. The contagion as a rule is contained in the fresh and still moist secretion of the nasal and bronchial mucous membranes.

As regarded the relation of the bacilli to the morbid secretions the author reports: they are found in enormous quantities in the nasal secretions, whilst ordinary nasal secretion is very poor in bacteria. In the acute stages of influenza, bronchitis, or pneumonia, the bacilli lie free in masses, the pus cells remaining quite free of bacteria; the more advanced the stage of the catarrh the more are these relations changed, so that during reconvalescence the great bulk of the bacilli are to be met with within the pus cells, where they show evidence of degeneration. In patients who recover slowly the bacilli are to be met with for weeks within the pus cells, and in the case of phthisical patients atttacked with influenza they may be seen for months along with the tubercle bacilli.

The author has never seen the bacilli in the blood, but he does not doubt the possibility of their presence within it, but he has repeatedly seen them in the kidneys and spleen.

Pathological investigation also afforded abundance of valuable material. The bacillus in the first bifurcations of the air passages mixed with other bacteria is alone present in the finer bronchial branches, and also in the lung tissue. Even microscopically influenza pneumonia is quite different from the croupous form. In the first named the individual lobular patches are distinct; these finally run together and form apparent lobar infiltrations. Microscopically excessive destruction of epithelium and enormous accumulation of bacilli can be determined, the lamina being filled with mucine substance and pus cells. In the lobular patches the central tissue is filled with round cells, laden with bacilli; no fibrin, no other bacilli. Influenza pneumonia may end in—(1) resolution and complete restoration; (2) in abscess formation or in the formation of cicatricial tissue within which influenza bacilli are still demonstrable; (3) in gangrene of the lung; (4) it may pass directly into caseous metamorphosis wherever the influenza infiltration has been established within tubercular tissues. On one occasion the author observed thick purulent deposits on the pleura which contained pure cultivation of the influenza bacillus.

As regards experiments on animals, his first were only successful on monkeys. When small doses were introduced into the trachea mild symptoms of disease were produced. In the case of one monkey to which a larger dose was given death took place within two days with symptoms of great prostration and lowering of temperature. Examination *post mortem* showed that no increase in the bacilli had taken place, but that a toxic action had brought about the fatal result. No true infection was set up in any of the animals experimented on.

QUININE AND INFLUENZA.

The *Deutsche Med. Wochensch.*, 51/93, contains an article on this subject by Dr. Graeser, Director of the German Hospital in Naples. As early as 1889 the author was struck with the resemblance of influenza to malarial disease, and he made use of quinine in the treatment of it in the Bonn Poliklinik with good success. From this he proceeded to the use of it as a prophylactic, and tried it on the Hussar regiment then quartered in Bonn, upon which General-Surgeon v. Coler reported as follows: "In Bonn the troops of a squadron received for 22 days 0·5 grm. of hydrochlorate of quinine daily in 15 grm. of brandy. This did not prevent the disease breaking out, but the number of sick in the squadron was certainly smaller than in the other squadrons similarly situated. During the experiments the numbers of sick were—in the 1st squadron 22, in the 2nd 7, in the 3rd 19, in the 4th 42, in the 5th 32. The second squadron was the one to which the "quinine schnapps was given." Of the 7 sick of the 2nd squadron 3 might be excluded, as they sickened on the first day of the experiment. The other four cases sickened, two on the 4th day, one on the 5th, and one on the 6th. No other cases occurred in the 2nd squadron, whilst the disease continued its course in the others. The author, on the basis of his experience and the experiments described, believes himself justified in concluding that quinine acts specifically in influenza, and that if given at the proper time and in proper doses it is capable of warding off the disease. As Binz also requires, it must not be given in divided doses, but in one sufficiently large daily dose, and best in a state of solution.

Austria.

[From our own Correspondent.]

Vienna, Feb. 16th.

Billroth.

The "Aerzte Gesellschaft" was engaged this week in filial devotion and lamentation for their deceased President, the late Prof. Billroth. At the last meeting of the Society he took an active part in the discussion on the aneurysm of small vessels.

Prof. Dittel, who occupied the chair, which was hung around with wreaths, said that one of their brightest ornaments had passed from the living. Although all knew that Billroth had been suffering from asthma, due probably to fatty degeneration of the heart, yet the paralysis that cut him off so speedily was not expected. According to ancient custom, a brother professor makes a long, public, historical description of the life, virtue, and labours of the dead. This was intrusted to Prof. Benedikt, who gave a long and exhaustive account of the changes and improvements in Viennese surgery and literature in recent times.

Congenital Luxation of Elbow.

Ullmann presented a man with dislocation of the elbow from birth where the head of the radius was thrown forward, and the articular end of the humerus was left free. In addition to this, there was ischiadica on the right side. Injury or inflammation of the joints seemed to be absent in their origin, although rachitis might be assumed.

Tumours in the Bladder.

Prof. Von Frisch gave a lecture on our operative knowledge of tumours in the bladder. He said that surgeons differed greatly in their description and removal of these tumours. Some were inclined to operate on innocent neoplasms, others carcinomatous which also gave different results. Albaren operated on 48 innocent growths, 36 healing perfectly; 97 cases of carcinoma on the other hand, were operated on, 43 of these improved, half of the number died, 23 only were cured. Prof. Dittel, in his statistics, operated on 25 tumours by the sectio alba, and 3 only were cured. In statistics of this kind, the diagnosis of the neoplasm is an important factor, and should be held out as the guide. Some are inclined to class all villous growths which may go on for ten years bleeding and yet remain innocent as carcinomatous. He had himself, operated on 14 cases, and microscopically examined, there were 7 papilloma, 6 carcinoma, and 1 adenoma. In all the cases except two the diagnoses were made by Nitze-Leiter's cystoscope. The size of the tumour and the constant bleeding often makes this diagnostic sign a difficult task as it darkens the prism. Again the size of the tumour is difficult to measure although we know that the object seen must be 28 millimetres which would make it about four times greater than it really is. Another diagnostic aid is the chemical examination of the urine although the distinction of carcinoma from all enlargements, chronic inflammation, &c., are impossible by this means. In all the 14 cases he had operated on none had died. Sectio alba was performed in all cases except two. In one carcinomatous case the posterior part of the bladder with the vagina was removed. In another case the carcinoma was removed through the rectum, taking away a large part of the bowel. The resection method at the pubic symphysis has not met with a favourable reception. The average duration of healing in these 14 cases was 3½ weeks. The method adopted was that described by Trendelenburg, the lower part of the bladder being illuminated by a cystoscope passed in through the opening, the tumour removed by means of long forceps and curved scissors. The mucous membrane healed kindly without sewing; the drainage was conducted by Dittel's knee pipe and the large wound supported by adhesive plaster. Of the seven innocent papilloma three were situated on the trigonum. One of them, a little more than the size of a pea, situated on the hypertrophied prostate caused often alarming hæmorrhage. The others were multiple neoplasms ranging from 7 to 20. The most of them were situated above the mouths of the ureters. One of the cases, a girl, æt. 9, with adenoma, was interesting from the fact of stone having been diagnosed; the urine was phosphatic and the neoplasm incrusted with a thick layer of lime. Three cases of carcinoma were removed by the thermo-cautery and scoop.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Laparotomy for a Case of Dilated Stomach.—Division of Adhesions.—Mr. **Pearce Gould** operated on a man, æt. between 30 and 40, who for several years had suffered with symptoms of a dilated stomach, vomiting, pain in the epigastrium, emaciation. He had been under treatment in the wards of the hospital on several occasions. The stomach had been washed out and a certain amount of improvement had resulted. This time he returned to the hospital weaker and more emaciated than before, having been unable to do any work for the last twelve months; the stomach was considerably dilated, there was no tumour nor induration to be felt; the man complained of constant pain two inches above the umbilicus; there was no clear history of gastric ulcer. An incision was made in the median line above the umbilicus, exposing the pylorus; the finger was easily passed through the pylorus by dimpling in the duodenum or the stomach; the coats of the latter were thinned; this exploration with the finger showed that there was no contraction of the pylorus. A delicate peritoneal adhesion was found passing from the anterior wall of the stomach across the pylorus and duodenum to the under surface of the liver, and a second from the great omentum passing also to the liver; these were dissected off and removed; no other adhesions were found. The abdominal incision was closed with three layers of sutures. Mr. Gould remarked on the difficulty of exact diagnosis in such cases before laparotomy; the long course of the case and the absence of any tumour in the epigastrium rendered it very improbable that the symptoms were due to a malignant growth, but he referred to a case on which he had operated a week previously where the symptoms had lasted thirteen years and in which no tumour was felt, but when the abdomen was opened a considerable malignant infiltration of the posterior wall of the stomach was found. For that case he did a gastro-jejunostomy. Narrowing of the pylorus, he said, might occur without any clear symptom of ulceration, and the presence of adhesions about the pylorus might produce all the symptoms of pyloric obstruction. He referred to two cases recently published by Mr. Mayo Robson in which the division of such adhesions had been followed by complete relief of all the symptoms. In the absence of any growth or narrowing of the pylorus he believed that in the case just operated on the symptoms were due to the delicate adhesions which he had removed, and he anticipated that the patient would be relieved by the simple operation he had done. Adhesions about the pylorus, however, he pointed out, might be associated with true stricture of the pylorus; it was important, therefore, to remember *that the size of the pyloric aperture could be ascertained without opening the stomach by dimpling in the anterior surface of the duodenum;* the finger could thus examine the pylorus as accurately as by introducing the finger into the stomach. Had he found the pylorus itself narrow he was prepared to perform the operation of pyloroplasty.

Inguinal Colotomy—Simple Method of Immediate Opening.—The same surgeon operated on a woman, æt. about 70, whose rectum had been excised for cancer some time previously. She had been admitted in the present instance with signs of acute obstruction; the belly was greatly distended; there had been frequent and stercoraceous vomiting, and the patient was in great distress and very feeble. Mr. Gould at once performed left inguinal colotomy. He found the intestines injected and greatly distended, and reddish serum in the peritoneal cavity. On passing the finger into the wound a malignant growth was found at the brim of the pelvis. A loop of the sigmoid flexure was drawn out, fixed by a mesenteric stitch to the outer edge of the wound, and by a fixation suture at each end; three other fine sutures united the bowel to the inner edge of the wound; these sutures were all passed through the skin only of the abdominal wall. A pad of cyanide gauze with a large hole in the centre was placed over the bowel and surrounding skin, and the edges of the hole in the gauze were pressed into the groove around the loop of intestine. A longitudinal incision three-quarters of an inch long was made in the convexity of the loop of bowel in the longitudinal and muscular band; into this the flanged end of a straight glass tube was quickly slipped, and the bowel tied around it. A dressing of wool was then applied around the tube and retained in place by a binder, the tube passing through a hole in the binder. A cork was fixed in the outer end of the tube, The nurse was instructed to remove the cork whenever motion appeared in the tube. In this way Mr. Gould pointed out the contents of the bowel could be readily evacuated without even soiling the dressings or danger of infecting the peritoneal cavity. The glass tube he used was specially made for the purpose, being much like a Keith's glass tube without the lateral holes. He remarked that in cases of emergency he had used an ordinary test tube after cutting off the enclosed end. It was a great advantage, he thought, for these patients to observe perfect rest after the operation; the avoidance too of all change of dressings he considered of great importance.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

Necrosis of the Popliteal Surface of Femur.—Mr. Edmund Owen operated on a child, æt. about 8, who had a considerable enlargement of the lower end of the femur. He remarked, that although there was a little fluid in the joint, it was not a case of articular disease. In tubercular disease the joint ends of the bones are not enlarged; they undergo a rarefying ostitis, but not expansion. He said that the proper situation from which an attack should be made upon the femur was in the interval between the ilio-tibial band and the biceps. Making a free incision at that spot, he introduced his finger between the popliteal vessels and the bone, and discovered a small opening in the back of the femur. By the use of a strong raspatory he then raised a triangular sequestrum from the back of the femur just above the condyles, and he also extracted a sequestrum from the interior of the bone. After using a sharp spoon, he demonstrated a large cavity in the lower end of the diaphysis of the femur, which he washed out with a chloride of zinc lotion. Mr. Owen said that this was another instance of the proneness of the delicate tissue at the end of a diaphysis to be invaded by destructive micro-organisms. The case was probably one of acute septic osteo-myelitis in a somewhat limited area. Not unfrequently, if the original disease were allowed to run on unchecked, the joint became the seat of suppuration, and amputation had to be resorted to. The condition of popliteal necrosis occurred especially in children, though it might be met with at any time before the epiphysis was ossified on to the shaft. When in the course of the acute inflammation the dense popliteal surface of bone became invaded, a characteristic sequestrum such as he had just extracted was often met with. The frequency with which necrosis attacked that particular piece of bone was, in his opinion, due to its close proximity to the inflammable tissue of the diaphysis, in which septic as well as tubercular disease was very apt to start.

◆

Thirty-two nations will be officially represented at the International Medical Congress in Rome. Up to the present the officials have been advised of upwards of two thousand communications to be presented to the Congress. All the *fêtes* which usually take place in carnival times have been postponed to the period when the Congress will be sitting.

A widow lady residing at Walton was fined £1 and costs, last week, for not having notified to the police that her dog was suffering from rabies. The animal had bitten a boy who is now at the Pasteur Institute, examination of the dog's carcase after death, by a veterinary surgeon, having revealed the presence of rabies.

The death has been announced of Dr. Pickering, of Monaco, at the age of 54. General regret has been expressed by the members of the British Colony there at his decease, for Dr. Pickering enjoyed a large measure of popularity among his compatriots.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 21, 1894.

THE CARE OF THE IDIOT AND EPILEPTIC.

Charitable England is, we fear, far behind in the consideration which it has given to this matter, and in the provision which has been made for the care of these unfortunates. A recent Royal Commission recommended, *inter alia*, (3) that power should be given to town councils, jointly or severally, to set up institutions for educable imbeciles out of the funds at their disposal, and (6) that educable imbecile children should not be left for any time in workhouses or lunatic asylums. Moreover, the Lunacy Act of 1890 expressly provides that the local authority of any county or borough may provide separate asylums for patients suffering under any *particular* class of mental disorder. The latter provision, *any particular class of mental disorder*, would, in Dr. Shuttleworth's opinion, meet the case of the epileptic. The epileptic genus is difficult to classify, and cannot be located medically under one heading, or, socially, under one roof. If Dr. Shuttleworth pleads merely for the epileptic idiot or imbecile prior to adolescence, we can quite understand and agree with the views so ably and forcibly propounded by him in the *Times* newspaper! For sane and insane epileptics the case is different—they must be separately dealt with. While it is unadvisable to deal with the epileptic insane separately from the general hospitals for all classes of the insane, it is advisable, indeed most desirable, that the juvenile idiots and imbeciles should be kept out of asylums, and provided for separately. The English mind has not wakened up to this question yet; it is content to sleep over it, and to delay looking into a question that means public expense. The case at first looks a hard one for the ratepayer, for official charity is now a considerable tax all over the country; but if it is looked into apart from maintenance grounds, the public necessity for such institutions will be plainly apparent. The educable idiot and imbecile left to the tender mercies of the streets, neglected physically and mentally, becomes in time a public nuisance, is sent to asylums to become worse, to learn by mimicry from the adult insane all that is vile and corrupt. Further, he is helpless, is trained to no work, and is therefore a deadweight on the routine of the establishment, and an expense more than the ordinary lunatic. Provide separately for such children, in time teach so far as their small feeble brains are capable of assimilation, discipline their habits, and you present to society a presentable, tidy, nice-mannered, useful member of the special community to which he belongs. His work may not be worth as much as his board, but it is a *plus* factor in the finances of the institution, whereas his neglected brother, brought up in the gutter, is a *minus* factor, and therefore a very serious charge upon the State. The weak point in the Lunacy Act of 1890, as Dr Shuttleworth points out, is that legislation here is permissive, not compulsory. Those who framed the Act had not the courage to go the full length; but shirked their grave responsibility in this matter, trusting to public opinion wakening up in time. While a permissive clause in many cases is safer and wiser than a compulsory one, this is a case where it is positively cruel. Dr. Shuttleworth has estimated that at least 18,000 idiots and imbeciles of all classes are under 20 years of age, and for the care of these in England institutions for an aggregate of 1,600 have been provided by the Poor Law, whilst the five charitable institutions accommodate about an equal number. This is a most deplorable state of affairs, and we trust that the correspondence begun in the *Times* will not end there, but that a rousing agitation and moral compulsion will be the result.

◆

THE ROYAL COMMISSION ON OPIUM.

There is one feature respecting the Royal Commission on Opium which stands out in bold relief, and that is that the longer it continues its work the more apparent becomes the fact that such an inquiry was absolutely uncalled for. The Commissioners have now been collecting evidence on the subject in India for upwards of two months, and despite the alarming allegations of the busybodies, nothing has been proved to show that the use of opium by the Indian population is actually deleterious to morals and health. To those who know India and the Indian people this result has in no way come as a surprise, indeed, from the first it was felt by the best authorities on the subject that the inquiry was ill-advised, quite unnecessary, and could only lead to a useless waste of public money. According to the *Indian Medical Gazette*, European and native, official and non-official, have almost unanimously condemned any interference with the opium habit in India, and have emphatically declared that the practice as generally carried on by the Indian population, with the exception of smoking *Muddut* and *Chundoo* in opium dens, is not one from which any injury to health has been noticed. On the other hand there is no doubt that as a sustainer of energy when hard work is to be done or great exposure to inclement weather is to be borne, a section of the Indian people find it to be invaluable. In declining years, too, when the vital powers are flagging, it is found to be of immense benefit, and the same advantages may be claimed for it in cases of malaria, rheumatism, fevers, and pains and aches generally. In all these instances the moderate use of the drug has proved to be nothing less than a comfort and a blessing. These are the conclusions arrived at by experts and others who are most competent to judge, and whose position in the country and intimate knowledge of the subject enable them to speak with confidence and conviction. Just, however, as might have been anticipated, the scientific evidence showing that the inquiry was from the first perfectly unnecessary, has been overwhelming. For example, one of the witnesses called by the Commission was Dr. Lethbridge, who has had twenty years experience of prison administration in India, and his testimony was to the effect that the use of opium, even in excess, did not in his experience lead to any organic constitutional changes such as those which resulted from the use of alcohol. "Even the emaciation," he says, "and the tucked-up appearance of the opium drunkard disappears very rapidly after the drug has been stopped." Again, a practitioner who had practised for thirty-eight years in Calcutta, and who had had as patients men of all castes, races, and religions, affirmed that he had not found that the opium habit was in any way productive of disease, and he further made the important statement that throughout his long experience he had never come across a case of opium drunkenness. Furthermore, the medical officer of a large opium factory testified that out of a total of 2,758 hands employed he had never met with any case of illness which he could trace to the effects of opium. Thus, judging from the numerous witnesses whose experience was similar to this, it would appear that the scientific evidence disproving the allegations respecting the deleterious results of the opium habit could be multiplied almost *ad infinitum.* Among the medical witnesses examined a unanimity to this effect was displayed which could not have failed to impress the Commissioners—and more especially must this have been the case, since the whole question must necessarily devolve upon the evidence of those whose calling brings them into direct contact with all classes of the community who have become inured to the habit. To the casual visitor to India there is nothing to indicate that any such habit as that of the indulgence in opium is resorted to; and yet, if the effects of the habit were so deleterious upon the population as have been described, it would scarcely be possible for these to escape the observation of persons who were new to the country and its people. Under the circumstances, then, with the strong testimony disproving the allegations which have been made, the question might well be raised whether any more money should now be wasted upon the inquiry. Sufficient evidence has surely now been collected to show that the inquiry was unneeded, and it is difficult to see that any good can come from the Commission prolonging its work. The busybodies who clamoured successfully for the Commission should now be called upon to contribute to the enormous waste of public money which the inquiry has involved. Had they been required to guarantee some of the expense they would not have been so eager to foist their folly upon the authorities. But the wonder is that the clamour of a small clique should ever have been listened to: any attempt to stop the consumption of opium in India would inflict just as much harm upon the population as has resulted from the repeal of the Contagious Diseases Act, which, again, was the work of a clique of irresponsible faddists.

◆

Cholera is officially reported to have broken out at Tripoli. Several cases of disease have occurred in the military hospital outside the town.

Notes on Current Topics.

An Anarchist's Death.

Since Thursday last the public mind has been deeply stirred by the horrible death of the French Anarchist, who was in truth "hoist with his own petard" in Greenwich Park on the evening of that day. The circumstances of the case have endowed the incident with details of such import that the political, social, and national questions involved have almost thrown into the shade every other matter of public notice at the present time. The story of the explosion of the bomb by which the wretched individual lost his life has been fully described in the newspapers, and circumstantially the evidence respecting the manner in which his death was brought about undoubtedly bears upon it the impress of truth. It is only, however, the aspects of the case which belong purely to our own profession that we need stop to discuss here. The man was killed, killed in a manner which was sufficiently revolting, and the nature of his injuries, arising from the explosion, was remarkable. Perhaps, however, the most extraordinary feature in the case was that the destructive force of the explosion was not more extensively displayed. With a bomb designed, as far as is known, for the destruction of a building, it is certainly surprising that the man was not practically "blown to pieces" when the explosion took place. The supposition is that the infernal machine exploded in one of his pockets, and yet, despite his injuries, the wretched creature lived for some time afterwards. With a view of ascertaining the precise details of the effects of the explosion a representative of the Medical Press and Circular paid a visit to the Seamen's Hospital at Greenwich on Saturday last. The post-mortem examination had just been made, and the full details of the injuries had therefore been carefully noted. Through the courtesy of the medical officers at the hospital our representative saw the body, and was informed in respect to the results of the post-mortem, and we are thus enabled to supply our readers with the material facts in connection therewith. In the first place the reports of the injuries in the public press have been much exaggerated. Saving for a few small abrasions of the skin the man's face was entirely unaltered, and it is not true, as has been stated, that either of his legs was broken. The lower two-thirds of the left forearm were blown off, and there was a lacerated wound of the abdomen on the right side, mainly involving the right hypochondrium; there was also an extensive rupture of the liver; the right kidney was also ruptured, and there was a lacerated wound in the lumbar region, which pointed to the fact that some large foreign body had passed through the abdomen, inflicting the injuries above mentioned, and had made its exit posteriorly. There were also flesh wounds of small extent upon both thighs and over the right pectoral region, in some of which portions of clothing and some pieces of metal were found. Despite the extensive rupture of the liver, very little blood had extravasated into the peritoneal cavity although the newspaper reports state that a good deal of blood was found on the pathway where the explosion took place. It may be added that the body was that of a decidedly small man.

Sir Richard Quain at Cardiff.

It goes without saying that anything which Sir Richard Quain, the President of the General Medical Council, says on the subject of Medical Education would be certain to be instructive and calculated to command attention, and in his address at the opening of the Cardiff Medical School last week he touched upon topics which were highly interesting. Among other things he alluded to the character of education and examinations in former days, and said that he could remember the time when the period occupied by examination, qualifying for a surgeon, held by the Royal College of Surgeons of England was one hour, one half devoted to anatomy, the other half to surgery. There was no preliminary examination in general education, and no examination in any other department of the healing art. The examination of the Apothecaries' Hall for the L.S.A., facetiously called by the students the "M.D. of Blackfriars," occupied about the same time, and questions were asked in the practice of medicine, materia medica, and botany. In the present day, however, the conjoint examinations of the Royal Colleges of Physicians and Surgeons occupied forty-one hours, of which the preliminary examination extended over fourteen, and the examinations in the several professional subjects occupied twenty-seven. Again, the time occupied by candidates for the degree of M.B. of the University of London was ninety-one hours, twenty-five of which were devoted to the matriculation examination, the three remaining examinations occupying the remaining sixty-six hours. He also drew attention to the remarkable fact that since the foundation of the University of London in 1842, the total number of candidates, at all the examinations, up to 1892, amounted to 87,442! In passing he paid a warm tribute to Dr. John Snow, who died in 1848. To him Sir Richard attributed the credit of having discovered that cholera was propagated by the use of drinking water contaminated by the cholera virus, a discovery which had been the means of saving, perhaps, millions of lives. The address throughout was intently listened to, and evoked an outburst of applause at its termination. The chair on the occasion was occupied by Lord Windsor, in the absence of the Marquis of Bute.

The Disease and Death Rates of Negro Convicts.

From a comprehensive series of statistics, Dr. Cunningham, of Ensley, Ala., draws some interesting conclusions respecting the disease and death rates of negro convicts. In a paper on this subject contributed to the "*Filadelfia*" *Medical News*, he shows that his figures point to the facts that there is a much larger class of diseases represented among the negro than among the white deaths; that the whites are more liable to die from accident, meningitis, and the continued fevers, than the negroes; and that the negroes are especially prone to tuberculous affections, the various forms of pneumonia, pleurisy, and organic heart disease, in short to thoracic diseases generally. In part explanation of this latter statement an examination of several thousand negroes showed that the normal thoracic movements in ordinary respiration were difficult, and that the thorax was not capable of as great movement during forced inspiration and expiration as in the whites. But if the negro is deficient in thoracic development he makes up for the deficiency in his abdominal development. The natural largeness of the negro's abdomen, as well as of his genitals is a conspicuous feature of his *physique* in comparison with white persons. The general muscular development, however, of the negro is good, saving for the deficiency of the chest muscles and those below the elbow and knee. The author concludes that the effects of prison life, however well ordered, are, regardless of race, beyond all doubt detrimental both to mind and body. In the white, the mind suffers most in consequence, and in the negro the body is most affected.

Small-Pox in a Love Letter.

Flirting with nurses is not without its dangers, and these are enhanced when the nurse is engaged in looking after infectious cases. Purity of sentiment is not enough to secure immunity from infection, and it is possible, within the narrow compass of a *billet doux*, to transport a tangible quantity of specific germs. Such was the experience of a "young man of Torquay," who languished after a nurse engaged in far away Yorkshire in looking after a number of small-pox patients in the local isolation hospital. It is just possible that something in the letter determined a depressed mental condition which is well known to constitute a predisposition to certain diseases. As to this we are not in the possession of precise information, but, be this as it may, the unfortunate suitor pined to such a degree that an eruption made its appearance which was declared by a competent authority to be small-pox. In future, nurses should either be forbidden to have "followers" while engaged on this kind of work, or special arrangements should be made to disinfect their correspondence. It will not be sufficient to use an antiseptic ink nor to sterilise the pen itself. A prolonged bath in a solution of corrosive sublimate or five minutes at the back of the grate will alone preclude the repetition of so regrettable an occurrence. Men, on the other hand, will be well advised if they fail to see nectar on a lip which is within dangerous proximity to a case of small-pox.

An English Medical Man at Kabul.

The Amir of Afghanistan recently had the benefit of the medical attendance of an English practitioner, and the latter, named Mr. John A. Gray, described his experiences as surgeon to His Highness in a paper read before the Society of Arts last week. Mr. Gray was a month in Kabul, and saw a large number of patients. The populace there flock to a European doctor. He found the Amir a man of good presence, broad and stout, fair-skinned, sun-burnt, and with black hair and beard. Dignified and courteous, on occasion the Amir can be exceedingly fierce, and no Chief dare speak or sit in his presence without permission. The medical work was heavy, remittent fever decimating the troops. So far as the Amir himself was concerned, his only complaint at the time was a common cold. Apparently the ruler of Afghanistan has yet something to learn from civilised nations. At all events, he seems to have one habit which leaves a good deal to be desired. In open durbar he generally makes a point of taking out his artificial teeth and cleansing them with a toothbrush, after which he replaces them in full view of his courtiers. The suggestion is made that this somewhat indelicate procedure impresses the people and gives them the idea that their king is one who can take himself to pieces at will. We are glad to know that the Amir is no enemy to vaccination, as is shown by the fact that he instructed Mr. Gray to vaccinate the young prince who is heir to the throne.

An Interesting Point in Retinal Physiology.

Dr. Frederick A. Cook, who was the ethnologist to the Peary Expedition to North Greenland, records some observations respecting the physiology of the retina which are worthy of note. He gave a native a photograph of an actress: but while paying the former a visit a few days afterwards the photograph was noticed to be hanging on the wall upside down. Dr. Cook remedied this state of things, but shortly afterwards the photograph was again placed in its original reversed position. This aroused his curiosity, and a series of experiments was carried out on other natives, with the result that without exception every individual who was handed a picture book at once inverted it, and then in awe and amazement began to examine the pictures. Evidence was then forthcoming to show that the individuals in whom this strange peculiarity was noticed had never seen a book, picture, printed or written paper before. One or two natives were subsequently asked to draw a polar bear, but when the drawing was finished the legs of the bear were upwards, that is to say, the image was inverted. Other images and pictures were drawn with the same result. The author accounts for this "inverted" phenomenon by assuming a want of education of the retina.

Exit the Indian "Oculists."

The curtain has fallen on the last scene in the drama of the "Indian Oculists." After the acquittal of these peripatetic practitioners at the Old Bailey a few months ago, they became so destitute that there was nothing left for them to do than to enter the workhouse. But their position as paupers was far from being a tolerable one to them, and yet they were entirely without means, and totally unable to obtain assistance by which they could accomplish their cherished desire to return to their own country. In this unfortunate and apparently hopeless condition of affairs the Secretary of State for India was successfully appealed to, with the result that he undertook to advance the passage money to these unhappy natives provided that they entered into an agreement to refund the money after their arrival in India. This agreement was naturally quickly completed, and the four men are now on their way to Calcutta—sadder, we should imagine, if not wiser men.

The Retirement of Dr. W. H. Dickinson from Hospital Practice.

Dr. W. H. Dickinson, for many years Senior Physician at St. George's Hospital, London, went round his wards for the last time on the 12th instant, and has now retired from the acting staff of the hospital. The severing of his long connection with an institution the pulse of which, so to speak, he had felt almost daily throughout his time, could not have failed to make his leave-taking an occasion of sorrow. The valedictory ceremony, therefore, which took place in the board-room of the hospital after the last patient had been seen, and the last word spoken to the students in his capacity as senior physician, was one which could not have been otherwise than affecting. Dr. Dickinson, however, bravely refused, as he expressed it, to be "sentimental," and thus the ceremony became more tolerable for those whose feelings are more easily touched, and to whom sorrowful scenes are a source of pain. An influential committee has been formed, headed by the Duke of Cambridge, to present a testimonial to Dr. Dickinson on his retirement.

Arsenic and Cancer.

Among the ingenious and plausible suggestions emanating from Mr. Jonathan Hutchinson is the possibility of the evolution of epithelioma being facilitated by a long course of arsenic. In his well-known paper on the subject he alleged a number of instances in which there was certainly presumptive evidence of arsenic having thus favoured the evolution of the cancerous outbreak. At a recent meeting of the Clinical Society *apropos* of a case of multiple epithelioma following a course of arsenic, he called attention to certain peculiar changes in the skin of the palms and soles which in his opinion indicate that it is time to desist from the administration of the drug, viz., a furfuraceous thickening of the skin in those situations. We call attention to this statement in order that our readers may avail themselves of any and every opportunity of ascertaining how far the suggestion is confirmed by clinical observation.

The Collapse of the Harness Case.

The solicitor of the Harness libel suit against a London evening newspaper has intimated that no further proceedings will be taken in the matter. The reason alleged is that it is useless to fight a millionaire, and that Harness has no funds with which to sustain a costly libel action. Probably the late manager of the Medical Battery Company has already had too much of the law courts, and is not anxious to brave the perils of another trial. The best that he can now do is to retire from public life, and in the seclusion of a suburban residence endeavour to find a solution to the problem of what use he has been in his generation.

The Coombe Hospital Scandal, Dublin.

The suit of Dr. Colclough Hoey, ex-Master of the Coombe Hospital, *versus* the *Independent*, for libel in connection with the recent *bouleversement* at the hospital, was in the law list of the Dublin Courts for last Monday, and will come on for trial in a few days. Several well-known Dublin physicians will be put into the witness-box, and it is to be expected that the rumours as to irregularities in the management of the hospital will assume a definite shape, and be the subject of cross-examination.

Irish Medical Schools and Graduates' Association.

The annual general meeting of the Association will be held at 11 Chandos Street, Cavendish Square, on St. Patrick's Day, Saturday, March 17th, at 6 p.m. On the same evening the Association will dine at the Café Monico, Piccadilly Circus, at 7.30 p.m., the President, Richard Heath, Esq., M.D., in the chair.

The Premier's Eyesight.

A London evening newspaper last week quoted a sensationally-worded report to the effect that the Premier was suffering from complete cataract of one eye and advancing cataract in the other. The report was embellished with an account of the observations which Mr. Gladstone is stated to have made when the information was conveyed to him by his medical adviser at Chester that the failure in vision was due to the cataracts. There and then, so the report runs, Mr. Gladstone wanted the completely opaque lens removed. "I want you," he said, "to perform the operation here and now, while I am sitting in this chair." "It might not be successful" added his medical adviser. "That is a risk I accept," retorted the head of Her Majesty's Government. The operation, however, was not performed, neither there nor then, nor has any confirmation of this extraordinary incident appeared in the public press. Mr. Gladstone's great age would form no insuperable obstacle to the performance of a cataract extraction, if such an operation became necessary. But while his extraordinary vigour has kept him mostly free from the infirmities of age, it is only right to mention no authoritative statement has yet appeared to the effect that he is suffering from cataract.

The Paragrapher on Electrical Appliances.

The average journal devoted to women is remarkable for the number of advertisements which are inserted in the body of the paper under the guise of didactic paragraphs. Seldom, however, have we seen a more misleading passage of the sort than one which appeared a short while since in the columns of a fair contemporary. After referring to the caution which is needed now-a-days in dealing with electrical appliances, the writer boasts that a certain notorious apparatus of that kind has never been recommended in the pages of his paper. After this little laudatory flourish he proceeds to make up for past abstention by describing an appliance about which several of his friends are filled with enthusiasm. Although the name of this therapeutic agent is a hybrid of which the first half is "electro," yet we are told that it does not lay claim to electric properties. Its inventor, however, claims that it generates pure atmospheric oxygen, and thus possesses properties that "purify the vital organs and restore nerve power in cases of general debility and neuralgia." One would like to know whether the oxygen is generated outside the body, as in that case it would be superfluous, since the gas already exists in the air in large quantities. Or is the appliance supposed to create oxygen in the actual tissues themselves? In the latter case actual disintegration of the tissues would inevitably follow, with results that could not fail to be disastrous. The whole passage is a fair sample of the nonsense that is offered to the public by editors who are interested in puffing quack appliances of a worthless description. Such statements as we have quoted will not bear a moment's candid examination. One would like to know what amount of hard cash the editor of the ladies' paper in question draws, or has drawn, or is likely to draw from the insertion of advertisements in favour of this infallible oxygenator.

"Place aux Medecins."

The narrative of the very narrow escape of the Atlantic liner *Cerean* from foundering brings into prominence the courage, firmness, determination, and self-sacrifice which is commonly manifested by members of our profession in the hour of danger. When the engine-rooms were flooded, the fires put out, and the leak gaining, the surgeon in charge, Mr. Smith, of Glasgow, a mere stripling, was the organiser of the pump hands, himself taking part of the labour and knowing neither sleep nor rest while he kept the men to the work. Were it not for his encouragement and example, despair might have overtaken the crew and passengers, and the ship would probably not have been where she now is, safe in dock.

False Teeth for Paupers.

The Local Government Board for England has decided that it has no power to surcharge the Chichester Guardians with £4 4s. paid by them for a set of artificial teeth for one of the recipients of out-door relief. Heretofore the duty of the taxpayer to the pauper has been considered to be discharged when the pet has been supplied with wholesome food and such luxuries as tobacco and whiskey. It seems, however, as if we had come to the time when Guardians must follow the dominant craze, and as School Board "Progressivists" have provided pianofortes and tennis rackets for the children of the omnipotent artisan, Guardians must find artificial dentures for the charity pensioner. Let us hope that the authorities will not insult the nobility of the unemployed by offering them cheap vulgar vulcanite instead of the more proper gold plate!

The Factory Acts.

The Home Secretary, Mr. Asquith, has intimated his intention of introducing a Bill to amend these Acts. This may be interesting to factory surgeons, considering that they narrowly escaped extinction by Mr. Matthews, the late Home Secretary, who desired to expunge them, but was prevented doing so by an adverse vote of the Select Committee to which the Bill was remitted.

An Open Sewer in London.

The insanitary condition of the Regent's Canal has frequently been pointed out, but the Report of the Public Health and Housing Committee of the London County Council just issued shows that the canal is little else than an open sewer. The disclosures contained in this report reveal a state of things which is a positive disgrace to the metropolis. Of course, the Canal Companies concerned are not short of excuses when remonstrated with on the subject. Among other things, they state that the stagnant condition of the water was incidental to all canals which did not canalise rivers, and that it was not in their power to pass more water down the canals. It was also pointed out that the Zoological Gardens is Crown property, and, despite this fact, nothing had ever been done for the diversion of its sewage from the canal into the public sewers. We are glad to see that the Committee above mentioned expressed its conviction that legislation was urgently wanted to enable the County Council to deal directly with the canal in its course through London. The local sanitary authorities may remonstrate with the Companies, and direct certain things to be done so far as their power lies, but such remonstrances in the past seem to have been in vain, and until more stringent powers are obtained, it is scarcely to be expected that the sanitary condition of the Regent's Canal will be found to be any better.

"Scares."

When a wave of sanitary hysteria passes over the public, the sanitary enthusiasts, and the medical profession, it is a great mistake for the practitioner who desires popularity to hesitate about joining in the general cry. He may know—no one better—that three-fourths of the statements in the newspapers, and two-thirds of the horrors to which those statements give origin, are nonsense, and that the lapse of a few months will explode the entire fabric of theory and hasty conclusion, but if he is wise, he will add his voice to the cry, and make what he can out of it in the way of notoriety and fees. The Koch craze was a case in point, the hydrophobia scare is another, and the cholera screech of last year is a third illustration. While the hot fit was on, all sorts of projects for drastic sanitation were put in practice, quarantine *cordons* were established, the police were stirred up, and new hospitals were designed on an extensive scale. The real truth comes out now. The Medical Officer of the London County Council reports that fifty cases of alleged cholera were investigated. Of these, only thirteen were considered worthy of scientific examination by Dr. Klein, and of the thirteen only three presented the pathognomonic comma bacillus. This is but a small residuum of proof for the vast quantity of assertion, and it teaches us to avoid screeches and crazes, and calmly, but without losing time, to investigate and inquire before delivering ourselves over to the epidemic hysteria fit.

More Compulsory Notification.

It will be observed from perusal of our remarks upon lead-poisoning in our last issue that the latest suggestion of the notificationists is that every case of plumbism shall be notified under penalty, which, it is naïvely suggested, becomes necessary "because at present persons thus affected avoid the medical officer of the works lest he might stop further employment." Exactly so. But why not, on the same principle, fine and imprison all bootmakers or chiropodists who omit to notify corns, and all dentists who fail to report dental caries, or, still more reasonably, all practitioners and chemists who do not report syphilis and gonorrhœa? Was ever a hobby ridden to the death like the notification hobby?

The New Chinese Medical College.

Surgeon-Captain Heuston, F.R.C.S.I., has been appointed Director and Professor in the new Chinese University at Tientsin, which was opened in October last, with sixty students. Its purpose is to educate Chinese for the medical profession in order that they may be able to take places in the army, naval, and civil services of their country. Surgeon-Captain Heuston will have under him pure Chinese doctors, educated and graduated in England, and the new college bids fair to become a very important institution.

The Physiciancy of the City of Dublin Hospital.

The succession to Dr. Hawtrey Benson in this position was decided last week by the appointment of Dr. Alfred Robert Parsons, Assistant Physician to Sir Patrick Dun's Hospital. We have already informed our readers that, upon the resignation of Dr. Benson, eight candidates offered themselves, of whom the Medical Board selected three, viz., Dr. Broomfield, Assistant Physician to the Hospital; Dr. Bewley, Assistant Physician to the Adelaide Hospital; and Dr. Parsons. This selection was sent to the lay Board of Governors, and eventually they chose Dr. Parsons. The new physician is a young man who has no claim upon the hospital as one of its own *alumni*, but who has achieved much distinction in his University career, both in Arts and in Medicine. He is an A.B., M.B., B.Ch., and B.A.O. of the University of Dublin, dating from the year 1888, but, in addition, he took a senior gold medal in experimental physics, and was the Medical Scholar and Travelling Prizeman of his time. He pays something like £1,000 to the outgoing physician, that being the proprietary interest of the place, in respect of money originally invested by his predecessor in founding and carrying on the hospital. It ought to be understood that this payment is in no sense a bribe, but is a fair and honest recoup of capital invested, and it does not influence the election in the least degree. The legal arrangements made some years ago when the lay Governors took the subject in hand provide for the gradual extinction of these proprietary claims, as is quite right and proper.

Alleged Discovery of an Opium Antidote.

The detailed description of an alleged discovery of an antidote to opium by a New York physician is going the round of the public press. It is stated that the discoverer, Dr. Moor, gave a practical demonstration of his faith by swallowing three grains of morphia in the presence of a number of medical men. Immediately afterwards he took the antidote, namely, four grains of permanganate of potash, which, like the alkaloid, was dissolved in water. Contrary to the expectations of the medical men, who kept him under observation for the next five hours, he was uninjured by this heroic dose of poison. Dr. Moor is said to have hit upon his discovery by accident. He found that the permanganate, when added to a solution of morphia, not only precipitated the alkaloid, but also removed the characteristic taste. This action was almost instantaneous, but was considerably retarded in the presence of white of egg and peptones, substances which closely resemble what the permanganate would meet with in the stomach. Notwithstanding the probable hindrance to be looked for in that quarter, the doctor had the courage of his convictions, and carried out his *experimentum in corpore vili.* If this discovery be true, it would be almost impossible to over-rate its value. At least half of the total number of deaths from poisoning are due to opium or its alkaloids, and a specific antidote to the poisonous action of so deadly a drug would add a powerful weapon to the *armamentarium* of the practical physician.

A Medical Charter for Herbalists.

A person named Newton, who practises herbalism at Keighley, and is stated to be a prominent member of the Town Council, was prosecuted last week for breach of the English Apothecaries' Act of 1815, by engaging in medical practice. It was admitted that he had done so for nearly thirty years, charging 2s. per visit, and prescribing for all sorts of ailments. He pleaded the authority of an Act of 1542 passed "for the benefit of the poorer classes, by which it was permitted for persons having a knowledge of roots, herbs, and waters, to use and administer herbs, &c., for outward ailments, and to give drinks for stone, strangury, or ague." It was urged that the Apothecaries' Act did not repeal this statute, and that it is still operative. The Judge held that even if the Act was still operative it would not confer power to visit patients and prescribe for inward ailments, and accordingly he fined the herbalist two penalties of £20 each and full costs. It is worthy of remark that Keighley is the home and centre of anti-vaccinationism, and that the Town Council is notorious as the most obstructive and reactionary conclave in Great Britain as regards sanitary administration. This is not to be wondered at when a herbalist can boast of having visited and prescribed for nearly thirty years "without let or hindrance" under the authority of a charter passed in 1542 ! ! !

We understand that H.R.H. the Duke of Connaught has signified his intention of presiding at the Festival Dinner on behalf of the London Lock Hospital at the Hôtel Métropole on April 21st.

In consequence of the frequency of accidents at the Royal Gunpowder Works at Waltham Abbey, the War Office have, it is stated, determined to erect a proper hospital on the works, and a small staff of nurses will be permanently engaged for emergencies.

An announcement is made in our advertising columns that the "Nurses' Co-operation" intend to apply to the Board of Trade to be registered with limited liability, without the addition of the word "Limited" to its name. Any objection to the proposal must be made to the Board before March 16th.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Royal Colleges of Physicians and Surgeons, Edinburgh.—Negotiations are, we believe, proceeding between these two Colleges with regard to a closer relationship between them than formerly. For instance, the College of Physicians may combine with the College of Surgeons in the support of a research laboratory similar to the one at present conducted by the Physicians alone. A more visionary scheme is to, by a sort of amalgamation, form an Academy of Medicine in rivalry with the University. Whether this last scheme ever outgrows the fœtal stage or not, there is no doubt that a closer reciprocity between the two Colleges will be of advantage to both.

The Medical Officer of Annan and the Notification Act.—The Sanitary Committee of the Annan local authorities have agreed to request Dr. M'Bean, the M.O.H. for the burgh, to resign, not being satisfied with the manner in which he has carried out the provisions of the Notification of Infectious Diseases Act, which has lately been adopted in the burgh.

The Tyson Cure Again !—The favourable result reported from the Tyson experiments in Dundee—favourable because at the end of a few days a few drunkards said they were cured and had an absolute loathing for alcohol ! —has stimulated the Edinburgh teetotal faddists. They propose to try the cure among the "habituals" of the city in a short time. We would like to receive a report of the patients alleged to be cured in Dundee six months after the course of treatment. Could not some practitioner in that city advise us ?

Edinburgh Royal Maternity Hospital.—This hospital has again been opened ; D. C. Edinton, M.B., C.M., and W. C. Hamilton, M.B., C.M., will act as House Surgeons during the quarter.

Proposed Glasgow Medical College for Women.—The trustees under the will of the late Dr. Henry Muirhead have come to a decision regarding the disposal of £34,000, left by that gentleman to found a college for the instruction of women, chiefly in science and medicine. The proposal, made by the committee of trustees to the Court of Glasgow University, was rejected, to affiliate the proposed Muirhead College with the University, and the trustees have now decided to proceed independently of the University. Compared with other medical colleges for women, the means of the Muirhead College will be exceptionally large, and in conjunction with the Victoria Infirmary it will form the best-equipped institution for the medical education of women in the country. The degrees of the Glasgow University will not be available to students of the Muirhead College, but the University of St. Andrews will doubtless extend the same privileges it has already given to the Edinburgh Women's Medical Colleges. Women students will thus be enabled to take the whole of their five years' curriculum at the Muirhead College, and then graduate at St. Andrews University as if they had studied there.

The Criminal Responsibility of Drunkards.—Dr. J. F. Sutherland, Medical Officer to H.M. Prison at Barlinnie, delivered an address before the members of the Glasgow Eastern Medical Society last week. In the course of his remarks he said, the extreme penalty of the law should be enforced against the deliberate assassin, or the burglar who "removed" his victim without hesitation, but he contended that it was out of place to so punish the drunkards who, under the influence of drink, committed savage assaults which ended in death. His experience, extending over thirteen years as prison surgeon, during which he had appeared in thirty cases of murder and culpable homicide, satisfied him that in no case did the author of the crime deliberately and with a knowledge of right and wrong commit the assault charged. Professor Gairdner, in opening the discussion which followed, said that the simple act of intoxication was not privileged, because it was a voluntary act. He argued that if the law was to maintain the position that drunkenness was no excuse for crime, it must constitute drunkenness a crime in itself, and sternly repress it. They must hold that men were responsible for becoming habitual drunkards, and therefore he was not in favour of coddling them.

◆

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (February 19th) was devoted in its entirety to the discussion of a paper by Mr. Joseph White, of Nottingham, on "The Administration of Chloroform clinically Considered." This gentleman's experience goes back to the very introduction of anæsthetics, and forty years ago he brought a paper before the local medical society describing several hundred administrations of chloroform. That number now reaches upwards of 7,000, including 4,049 of chloroform, 798 of ether, 691 with nitrous oxide, and 1,433 with the A.C.E. mixture. He has never had a single death, though he narrowly escaped a disaster on several occasions. He reviewed the history of the earlier fatal cases, which, curiously enough, all occurred within a very short time of the administration being commenced. After discussing the conclusions formulated by physiologists and committees of investigation, he suggested certain precautions having for object to avert the untoward consequences which still follow the use of chloroform even in skilled and experienced hands.

Dr. Sansom, who has done valuable work in this direction in years gone by, protested against the teaching that it is best to give chloroform to begin with in strong doses, a teaching which he regretted to see had been supported by the conclusions of the Hyderabad Chloroform Commission, of which he highly disapproved. He pointed out that it was the nervous, and not the muscular part of the heart that gave way in chloroform narcosis, and he dissented strongly from the view that in human beings it was the respiration that succumbed before the heart, the very contrary being the result of his own observations. He animadverted on the danger attending the ordinary method of giving chloroform, of administering too highly charged a vapour, pointing out that 1 per cent. of chloroform vapour was sufficient to secure anæsthesia. He scoffed at the idea that fatty heart was often responsible for death under chloroform, pointing out that, as a matter of fact, fatty heart was an exceedingly infrequent cause of sudden death.

Dr. Hewitt did not think that the contracted pupil indicated a working degree of anæsthesia. In using the A.C.E. mixture, he pointed out that only small quantities ought to be poured into the inhaler at a time in order that the unequal rate of vaporisation might not prove a disadvantage.

Mr. Silk admitted that chloroform was a possibly dangerous anæsthetic, safety depending on the care and skill with which it was administered.

Mr. Rowell preferred to rely on fixation of the eyeball in preference to the condition of the pupil.

Dr. Benham insisted on the advantage of giving a dose of brandy before commencing the administration of chloroform.

Sir William Dalby urged that if patients knew the difference in the mortality between the use of chloroform and ether, they would probably select the safer anæsthetic.

Dr. Edmunds called attention to the advantages attending the use of Krohne's modification of Junker's inhaler, by means of which it was possible to regulate to a nicety the amount of chloroform vapour entering the patient's lungs.

Mr. White, in reply, said he almost constantly used Krohne's inhaler, which he considered a very admirable apparatus.

◆

THE MEDICAL DEFENCE UNION.

At the annual general meeting of the Medical Defence Union held on Feb. 7th, an animated discussion took place on the report. A vote of censure on the Council was proposed owing to the Council having undertaken to defend a member of the Union in an action brought against him by another member, in opposition to a resolution unanimously passed at the last general meeting, "that the funds of the Union should not be used to defend or support any action made against another member of the profession." In the case in question both litigants are members of the Union, and their dispute arose out of an assistancy agreement. The plaintiff applied for assistance to one of the secretaries, Dr. Leslie Phillips, who, in acknowledging the application, promised to place the application before the Council, but added that it was contrary to the usual custom of the Council to take up cases between principals and assistants. In consequence of this statement, the plaintiff withdrew his application. Later on, the defendant, who is a member of the Council, wrote to the other secretary, Dr. Bateman, asking the help of the Union, and no obstacles being placed in his way, the application came before the Council and was accepted by them. It was stated at the meeting that the Council did not know the plaintiff was a member of the Union, and, moreover, had heard nothing of his original application to the provincial secretary. In the absence of any knowledge of these important and elementary facts it was strongly urged on the Council to reconsider their position. It has hitherto been a maxim of the Union, and one especially insisted upon in the last report, that all differences between medical men should be settled, if possible, by arbitration. In the course of the meeting a member of the Council stated that arbitration was offered in this case, but had been refused by one side. On the other hand, the plaintiff emphatically denied that arbitration had been suggested to him. It appears, therefore, that the Council took up the case of a member who refused arbitration without giving the other party to the suit, also a member of the Union, an opportunity of accepting that method of procedure.

The President said that there were exceptional features in the case which had induced the Council to take it up, but as the matter was still *sub judice* he was unable to state those circumstances. Many members present expressed the opinion that no circumstances, however exceptional, justified the Council in acting contrary to the unanimously expressed wishes of the members at the last general meeting. The vote of censure was ultimately defeated, as many members who had expressed their disapproval of the course taken by the Council abstained from voting. Shortly after the meeting the plaintiff entered legal proceedings to prevent the Union prejudicing his case by advancing any further support to the defendant.

At the same meeting it was proposed to discuss the action taken by the Council with regard to the proposed amalgamation with the London and Counties Protection Society, but there was no time available for that purpose. The balance-sheet of the Union shows the satisfactory surplus income of £395 8s. 4d. That amount exceeds by a few pounds the deficit of the foregoing year.

A medical contemporary of last Saturday says:—"In London the Notification Act is a decided failure, the numbers of cases of infectious diseases and the percentage of mortality having largely increased since the Act came into force."

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

LADY "MEDICAL" MISSIONARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the Medical Press of February 7th, I referred to the above subject, and asked Dr. Routh a few simple questions regarding the pseudo "medical" missionaries, whom he and a few other gentlemen are trying to flood the country with. But instead of giving a courteous reply to such questions, he tries to assume the *rôle* of the "injured innocent," and in the Medical Press of February 14th, "haughtily" states, "I decline further correspondence with Dr. Rentoul." When a man elects himself the champion of pseudo-medical-missionaries—even when such are sent out to teach the niggers and other so-called "heathen"—he should be prepared to fight. I guarantee I shall come out of it with as clean hands as any other person. I have not yet started a college at which those who have neither the brains nor the money to take a proper qualification can be granted diplomas, nor do I try to make the Hindu "find salvation" through non-legitimate methods.

Now, sir, I have asked Dr. Routh to say whether it is true that Dr. W. M. Ord is still the "Examiner in Medicine" at the "Zenana Medical College," and further, is it true that Mr. T. Pickering Pick, and Dr. W. R. Dakin still act as "Examiners in Surgery and Midwifery," at this College? If Dr. Routh will not answer, then each reader must form his own conclusion. Anyhow, I mean to call the attention of the General Medical Council to the action of all medical practitioners who are now constituting themselves into medical examining and diploma granting bodies other than those legally qualified to do so.

If you can send out as "medical missionaries" to India and China only those who fail to pass a proper examination and go through the necessary curriculum at home, then I would suggest that these "blessings of Christianity" be held back for a time. All honour to true missionaries, and to the Golden Rule of doing to others—even in medicine—as you would wish your own wives and daughters to be done to.

I am, Sir, yours, &c.,
Robert R. Rentoul.

Liverpool.

*** We think our correspondent is arguing on a wrong hypothesis; the General Medical Council has no voice in, or control of, a matter of this kind, even supposing the instruction and diplomas are illegal.—Ed.]

DR. MORTIMER GRANVILLE AND HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am well content that Dr. Granville should continue to "praise homœopathy with faint damnation," as he does in his last article; but there are one or two points in it which ought not to pass without comment. It will be observed that though he heads his article "Homœopathic Claims to Discoveries of Medicines," he makes no attempt to substantiate his original charge against homœopaths of having claimed what is not their due. On the other hand he makes some notable admissions. He owns that he was "very successfully" and very pleasantly treated by a homœopath through a severe illness, having passed through a very different experience at the hands of eminent allopaths in a similar illness two years before. He admits, also, that he signally relieved some of his own patients by the use of homœopathic remedies; and yet, in the face of these weighty testimonials to the efficacy of the system, he allowed himself to be driven from it for no better reasons than a scare at the amount of trouble it entailed, and the fact that the statistics of the homœopathic treatment of pneumonia did not satisfy him. If Dr. Granville had inquired a little further he might have been reassured on the latter point. Dietl lost 7·4 per cent. of his patients under "expectant" treatment, whilst Tessier, under homœopathic treatment, lost only 6, a difference of 1·4 per cent. (not ¼ per cent.) in favour of homœopathy. This is not a very great difference it is true, but when we come to consider the length of time the illness lasted a very marked difference is shown—Dietl's patients averaging 28 days, and Tessier's only 11⅜. With regard to pile of books which so appalled Dr. Granville, I quite sympathise with him there. Most practitioners of homœopathy have experienced similar sensations to those he mentions when they have first realised the magnitude of the task before them, only they have differed from him in that they have refused to accept this as a reason for running away from or abusing the system. They have concluded that the tangible benefits they have seen and experienced warranted them in facing the difficulties, however great. But there is a right way of approaching the literature of homœopathy as well as a wrong, and Dr. Granville had the misfortune to hit upon the latter.

Regarding Koch's lymph, I was under the impression that the great bacteriologist took especial pains to filter and sterilise it before he allowed it to leave his laboratory to be injected into the tissues of patients. If there exists in it "a single germ" of living tuberculous matter, Dr. Granville ought to furnish his proofs at once for the benefit of any who may still be advised to undergo the treatment.

I am, Sir, yours, &c.,
John H. Clarke.

Literature.

SIR WILLIAM JENNER'S LECTURES AND ESSAYS ON FEVERS AND DIPHTHERIA. (a)

In common with the whole medical world, we extend a hearty and sympathetic welcome to this book, with the authorship of which the name of William Jenner—*vir nobilis ac clarissimus*—is identified.

No doubt, with the last decade of the nineteenth century well advanced, standing within measurable distance of the *fin de siècle*, it seems hardly worth while to argue the question of the separate identity of typhus and typhoid fevers. But we cannot forget that forty or fifty years ago this was the great *quæstio vexata* of medicine. There are those among us, indeed, who are still young enough to remember with what weighty words and philosophic reasoning William Stokes did battle for the doctrine of the unity of these continued fevers—though all in vain, for facts were too strong in the end for the illustrious physician of the Meath Hospital.

In the conflict of medical opinion, which began in 1810, when von Hildenbrand first clearly distinguished between typhus and enteric fevers, no voice was more clearly heard or with more commanding influence than that of William Jenner. In a series of admirable papers published between 1849 and 1853, he maintained that typhus and the so-called "typhoid fever" were as distinct as any two of the exanthemata. Although many years elapsed before the specific distinctness of these two fevers was finally, and we may say universally, recognised, Sir William Jenner's writings did much to settle the controversy. Hence, it is that we hail the volume before us as a historical record, for it contains reprints of these classical monographs with all their wealth of original research and clinical observation.

Sir William Jenner had good reason to believe firmly in the separate identity of typhus and typhoid, for, as he tells us in his preface, while collecting some of the facts, which are detailed and analysed in his papers, and all of which "were observed and recorded at the bedside and in the deadhouse by myself," in 1847 he caught typhus fever, and three or four years later, typhoid fever. The late Dr. E. A. Parkes, who was at the time Professor of Clinical Medicine at University College, London, and subsequently Professor of Military Hygiene in Victoria Hospital,

---

(a) "Lectures and Essays on Fevers and Diphtheria, 1849 to 1879." By Sir William Jenner, Bart., G.C B., M.D.Lond. and F.R.C.P., D.C.L. Oxon., LL.D.Cantab. and Edin., F.R.S., President of the Royal College, of Physicians from 1881 to 1888, Physician in Ordinary to H.M. the Queen and to H.R.H. the Prince of Wales, Consulting Physician to University College Hospital. Demy 8vo, pp. 581. London: Rivington, Percival and Co. 1893.

Netley, attended him in both illnesses, and had no doubt about the diagnosis in each case. Sir William mentions this incident because it was said at the time, "Before typhus and typhoid fevers can be said to be absolutely different diseases some one must be found who has suffered from both."

The seven papers republished in the handsome volume under review are accurate reprints of those which originally appeared in various journals and in the Transactions of certain societies. The only alterations or additions made by the author are contained in a brief note or two appended to some of the pages. This being so, of course we shall look in vain for any mention of the modern bacteriology and pathology of the diseases described. Eberth's *Bacillus typhosus*, Löffler's *Bacillus diphtheriæ*, Oertel's *Streptococcus diphtheriæ* are not even named. Notwithstanding, the richness of the clinical material, the soundness of the treatment, and the philosophic tone of the author's teaching—more even than the glamour of his name—will arrest and hold enthralled the attention of the reader.

The first monograph in the series which make up the volume is on the Identity or Non-Identity of Typhoid and Typhus Fevers. It was originally published in the *Edinburgh Monthly Journal of the Medical Sciences*, in 1849-50, and was afterwards reprinted in book form in 1850. The author did not follow, seemingly, the advice of Dr. Parkes, who on reading the manuscript recommended him to place the conclusions at which he had arrived in the forefront of his paper. "If, said Parkes, "you place the conclusions first, whoever is interested in the subject will read them carefully and then will read what follows to see how you prove the points which interest him."

Well, we all know the conclusions to which Jenner's researches led him. In no uncertain voice he proclaimed that "it is indisputably proved that typhoid fever and typhus fever are equally distinct diseases (as small-pox and scarlet fever); not mere varieties of each other, but specifically distinct, specific distinction being shown in typhoid and typhus fevers, as in small-pox and scarlet fever by the difference of their symptoms, course, duration, lesions, and *cause*."

But, after all, the great and abiding value of this splendid monograph depends on the wealth of clinical material with which it abounds. It presents an admirable description of the mode of attack of the two fevers, their symptoms, pathological lesions and cadaveric changes, duration, complications, and sequelæ—all these facts being recapitulated in a summary toward the end.

In this paper we have the definition of the "comavigil" of Jenner. "By this term," says the author, "I intend to express that peculiar condition in which the patient lies with his eyes open, evidently awake, but indifferent or insensible to all going on around him, and not what some writers on fever (*e.g.* Chomel) have meant by the expression, viz., that state in which a patient lies asleep for hours, and yet declares on awakening that he has never closed his eyes." (Page 32.)

Here, too, we notice the introduction into medical literature of the expressions—now familiar as household words—"mulberry rash" and "subcuticular mottling," applied to the eruption peculiar to typhus.

The second paper in the volume, on the "Identity or Non-Identity of the Specific Cause of Typhoid, Typhus, and Relapsing Fever," was read before the Royal Medical and Chirurgical Society, on Dec. 11th, 1849, and was published in vol. xxxiii of that Society's Transactions. It is followed by an Appendix containing the report of the interesting discussion which ensued on the reading of the paper, and in which Dr. A. P. Stewart, whose writing in 1880 did much to settle the question of the separate identity of typhus and typhoid—Dr. Baly and Dr. Charles West took part.

The third monograph consists of a series of papers on the whole question of continued fever, illustrated by cases collected at the bedside. This essay was published in the *Medical Times* in a series of twenty-one papers, which appeared from time to time in that journal between November 17th, 1849, and February 8th, 1851.

In his clinical description of typhoid fever in this essay, Jenner avows his dissent from the view entertained by Rokitansky, that "pregnancy offers an almost entire immunity from typhoid fever." "My experience," says our author, "is by no means in accordance with that of the celebrated Vienna pathological anatomist's (*sic*), and I know others have repeatedly met with examples of women large with child suffering from typhoid fever." This is altogether our experience also, but we cannot agree with Sir William Jenner when he adds: "Pregnancy is a very serious complication. A *very* large proportion, I will not say all, of such cases die." The pregnant patient is, no doubt, particularly liable to miscarry or to be prematurely confined, but apart from this, we do not know that she runs any more risk than a patient who is not pregnant, or a male.

In a foot-note on page 387 there is a full account of those markings in the skin, to which the name of *taches blenâtres* has been applied by Duvasse Forget, of Montpellier and others. No attempt is made to explain these curious epi-phenomena even in a foot-note, although Sir William is doubtless aware that they have of late years been proved to have no diagnostic importance whatever, since they are really pigmentations of the skin caused by the irritation of the pediculi.

At pages 392 and 393 an excellent short definition of the four diseases, febricula, relapsing fever, typhoid, and typhus, will be found.

The fourth essay included in the volume embraces three lectures on the Acute Specific Diseases, being the Gulstonian Lectures delivered at the Royal College of Physicians of London, in March, 1853. They were published in the *Medical Times* for the same year. Jenner is clearly no believer in the doctrine of the "Change of Type in Disease," for in the opening sentences of the third of this series of lectures he observes: "A glance at the history of epidemics will render it evident that each of the acute specific diseases we have now constantly among us has maintained its identity through a lengthened series of years in countries most distant from each, and in climates most varied. That each has presented from first to last the same group of symptoms, and the same order in their appearance; that no one of them is a new disease; that the symptoms of small pox, the order of occurrence of these symptoms, its chief varieties and its complications are to-day what they were two hundred years since, to go no further back, there cannot be a question. The same is true of scarlatina." (Page 447.)

In this same lecture there is an interesting section on "Pyogenic Fever," or the acute purulent diathesis which sometimes accompanies, but more often follows, the acute specific diseases. With singular prescience and acumen the author says that, pathologically the affinity of this disease seems to be with erysipelas. Of course he makes no mention of the *streptococcus pyogenes*, or the *streptococcus erysipelatis*—micro-organisms of the pathogenic group which have much to say to the production of Jenner's pyogenic fever. By the way, this term must be carefully distinguished from Murchison's "pythogenic fever," which is enteric fever supposed to have arisen within or without the body. As to the origin of the multiple abscesses of which Jenner speaks, we think that Sédillot is nearer the truth in assigning the circulation of pus corpuscles with the blood as the sole cause of disseminated abscesses. Certainly, when they occur in the lung they appear to be of embolic origin—minute septic emboli lodging in the peripheral or terminal branches of the pulmonary artery, and so setting up multiple abscesses in the lung tissue.

The fifth monograph is an address on the treatment of typhoid fever, which was delivered before the Midland Medical Society, at Birmingham, on November 4th, 1879, and published in the second volume of the *Lancet* for that year. This address is a masterly exposition of all that is best and most useful in the management of one of the most treacherous maladies that a physician is called upon to treat. "The treatment of typhoid fever," says Sir William Jenner, "is essentially rational." "I have never known a case of typhoid fever cut short by any remedial agent—that is, cured. The poison which produces any one of the acute specific diseases (to which order typhoid fever as much as small-pox belongs) having entered the system, all the stages of the disease must, so far as we know, be passed through before the recipient of the poison can be well. If the patient can be kept alive for a definite time the specific disease ends, and then, if no local lesion remains to constitute a substantive disease, the patient is well." (Pages 473 and 474.)

We are surprised that the author substains so high an opinion of teaspoonful doses of charcoal two or three times a day as correctors of fœtor in the intestinal discharges. No doubt he stipulates that animal rather than vegetable charcoal should be prescribed, and that the greatest possible care should be taken that the charcoal is an impalpable powder. It is hard to see how charcoal can retain its absorbent and deodorant properties once it has been moistened, and certainly a teaspoonful of dry charcoal powder seems a distasteful meal, particularly when given to a perhaps half-conscious typhoid patient, passing fœtid and ammoniacal stools.

Needless to say, the modern methods of inducing intestinal antiseptics in enteric fever are not mentioned—such as the administration of salicylate of bismuth, absolute phenol and opium, thymol, and naphthol, and last, certainly not least, thiocamf in keratin-coated capsules.

The author's remarks on the administration of alcohol to avert death from failure of the heart power and to stimulate the nervous system are admirable: "It should only be given," says he, "for the purpose of attaining a definite object; its effects should be watched, and the dose so regulated as to attain the desired effect from as small a quantity as possible." (Page 492.)

The excellent essay on the treatment of typhoid fever is followed by two lectures on Diphtheria, its Symptoms and Treatment, originally published in 1861, when this fell disorder was making its uncanny presence felt in London for the first time. These lectures, as the writer says in his preface to the original edition, "are dogmatical in tone, because they are addressed to students, and I believe dogmatism to be essential for successful student teaching."

The present notice has run to so great a length that we can pause only to allude to a statement by Sir William Jenner, which seems to us to be open to misconception, and likely to lead to untoward, if not disastrous, consequences. It is to the effect that the occurrence of diphtheria is not immediately related to bad sanitary surroundings. "These facts," says the author, "are strong evidence in favour of the opinion that the ordinarily reckoned anti-hygienic conditions are not especially favourable to the development of diphtheria." Again, after enumerating a series of cases to prove the influence of family constitution in favouring the occurrence and determining the ending of diphtheria, he observes: "In all these cases the hygienic conditions were good; there was nothing patently bad as regards drainage, ventilation, overcrowding, water supply, food, or work. All the patients were in the middle rank of life, and resided in good-sized houses, and in fairly open situations." (Page 526.)

No physician at the present day will, we think, be found to deny a first rank to family constitution among the predisposing causes of diphtheria, and to assign to contagion the *rôle* of the exciting cause—the *causa causans*—of the disease. But it is a most dangerous doctrine to exclude from the list of predisposing causes insanitary conditions and particularly defective sewerage. Even supposing that these conditions had no direct influence in predisposing to diphtheria, the sore-throats which result from the constant inhalation of sewer-gas undoubtedly present a fertile soil for the development and culture of the pathogenic microbe or microbes of diphtheria. And, further, these pathogenic organisms certainly flourish in sewage-reeking soil or sewage-polluted water. At this moment we can recall more than one most striking illustration of these statements, but space fails us, and we content ourselves with mentioning the fact.

Sir William Jenner, impressed by one remarkable case in which the operation undoubtedly saved life, pleads for tracheotomy as a means of treatment—even if it is a desperate means. In the adult, laryngotomy is to be preferred to tracheotomy.

The volume before us draws to a close with an eloquent and instructive clinical lecture on Croup and the diseases that resemble it. This lecture was published in the first volume of the *Lancet* for 1875. It is particularly interesting because of the full description of laryngismus stridulus with which it opens, and because of the change of opinion which the author avows as to the identity of membranous inflammation of the larynx, or true croup and diphtheria. "I am inclined now," he says, "to the belief that there is no such disease as idiopathic, simple, membranous inflammation of the larynx, I say, I am inclined to this belief. I am not sure that it is true; but as I formerly thought that the weight of evidence was in favour of their non-identity, I am now inclined, from my further experience, to think that the two diseases are really identical, that the so-called croup is really diphtheria." (Pages 564 and 565.)

Thus ends this noble work, the perusal of which has brought to us pleasure and profit. It is fitly dedicated to the memory of Professor William Sharpey, Professor Edmund Alexander Parkes, and Sir James Clark, Bart., K.C.B., Physician in Ordinary to Her Majesty the Queen —"three of the most able, honourable and kindhearted men that the author has ever known in the Medical Profession."

GOODALL ON THE MICROSCOPICAL EXAMINATION OF THE HUMAN BRAIN. (*a*)

A WORK of this kind has been much needed, for the investigations in this field of medical research are now very numerous. The results of such labours are not, however, proportionate to the zeal and energy expended, probably because training in microscopic work is so often defective, and information is so scattered through the immense sheaves of medical literature now broadcast. Dr. Goodall was eminently fitted by position and experience to write such a book, and he has done so in a business-like way without circumlocution, and without waste of words. The scheme of the book is comprehensive, dealing first with fresh methods, then in turn with injections of cerebral blood vessels, hardening methods, fixation and stains. In addition, there is given as an appendix, a scheme for systematic post-mortem examination of the brain and its covering. The only noticeable defect in the book is the absence of a table of contents, a preliminary synopsis of this kind being now so general in scientific works that it is invariably looked for. Apart from this, it is a good useful book, which ought to prove invaluable to all asylum medical officers.

CURE OF RODENT CANCER BY ELECTRICITY. (*b*)

IF this book contains one original idea, it has escaped our search. The historical retrospect of the disease shows that the author is unaware that it was described by Arthur Jacob, of Dublin, years before any of the writers whom he names were heard of. The pathological review of the disease is a weak epitome of the ideas of previous authors —some of them undistinguished—the electrical disquisition is a paraphrase of any of the minor mamals on the subject, and the published experience of the author is limited to four very common place cases. The work is small and ought to be cheap, and it may be found useful for circulating amongst patients who suffer, or think they suffer, from rodent ulcer, and may be induced to think that they can be cured by the author's method.

THE CLINICAL SOCIETY. (*c*)

THE present volume comprises the proceedings of the Society from October, 1892, to May, 1893.

The communications number forty-three, and they are all of a practical character, and such as the general practitioner may read with ease and advantage. They contain no fine-spun theories, but deal with difficulties that present themselves at the bedside, and the whole statement is made in plain idiomatic English. To those familiar with the Transactions of the Society no word of praise is necessary, and to those to whom the Transactions are unknown the barest recital of the wealth of information they contain would appear as a great exaggeration.

(*a*) "Microscopical Examination of the Human Brain." By Edwin Goodall, M.D. Lond. Baillière, Tindall, and Cox. 1894. Price 5s.

(*b*) "The Healing of Rodent Cancer by Electricity." By J. Inglis-Parsons, M.D., M.R.C.S., M.R.C.P., Hon. Fellow American Electro-Therapeutic Association, &c. London: John Bale and Sons. Crown 8vo, pp. 82.

(*c*) "Transactions of the Clinical Society of London." Volume the Twenty-sixth. London: Longmans, Green and Co. 1893.

We recommend all our readers to become subscribers for these Transactions, confident that those who take our advice will be grateful to us for introducing to them one of the most practical, advanced, and trustworthy of medical serials.

◆

Medical News and Pass Lists.

The International Medical Congress, Rome.

The Hon. Sec., Mr. G. H. Makins, F.R.C.S., has sent us the following notes of latest arrangements:—It has been arranged to issue the various travelling tickets from Genoa until February 28th, instead of February 15th, as previously announced. Intending members should therefore apply direct to Professor Maragliano, Genoa. After March 1st application must be made to G. H. Makins, 47 Charles Street, Berkeley Square, London, W. Members enclosing their subscriptions to Professor Maragliano should make them payable to L. Pagliani. The member's fee is £1. The fee for guests, 8s.

The Employment of Women in Factories.

In the Labour Commission Blue-book on the employment of women an interesting account appears of the thoughtful measures provided by the well-known firm of cocoa manufacturers, Messrs. Cadbury, for the amusement, comfort, and general well-being of their female workers. The lady commissioner who contributes the report asserts also that the firm has the reputation of paying the best average wages in the Birmingham district, which means that the average wage of the majority of girls in its employ is higher than that of the majority of girls in any other factory. As showing, moreover, how attentive the firm is to the health of its workers, we note that it is the special business of a district nurse to visit the girls who are ill, and that a committee of forewomen meets once a week to give out tickets that may be required for hospitals or other charities.

The Sanitary Institute.

The Council of the Institute have accepted an invitation received from the Lord Mayor and Citizens of Liverpool to hold their next Congress and Exhibition in that city in the autumn of this year.

University of London.

The following is an official list of candidates who passed the recent entire Intermediate Examination in Medicine, alphabetically arranged:—

First Division.

Dodgson, R. W.
Drury, E. G. D.
Dyball, B.
Huggins, S. P.
Leicester, J. C. H., B.Sc.
Noble, H. P.
Waldron, F. T.

Second Division.

Chandler, F. W.
Dixon, W. E., B.Sc.
Farrant, M.
Flint, E. C.
Frazer, W. D.
Goring, C. B.
Green, H.
Hull, C. E.
Innes, H.
Ketchen, A. D.
Maxwell, J. P.
Patch, W. S., B.Sc.
Robertson, J.
Savage, W. G.
Scowby, E. T.
Thomas, R. T.
Tucker, E. F. G.
Waterhouse, R.
White, S. E., B Sc.
Wilkins, W.
Wise, H. M.

Nineteen others passed at the same examination, excluding Physiology, and eleven passed in Physiology only.

Royal College of Surgeons of England.

The following gentlemen, having passed the necessary examinations, have been this month admitted Members of the College. The names are arranged alphabetically:—

Allen, William Herbert, L.R.C.P. Lond. Appleyard, Francis Edward, L.R.C.P.Lond. Austin, James Herbert, L.R.C.P.Lond. and M.D. Toronto. Axford, Sidney Bertram, L.R.C.P.Lond. Bannerman, George Douglas King, L R.C.P.Lond. Barrow, Arthur Sibert, L.R.C.P.Lond. Barrow, George Augustus, L.R.C.P.Lond. Bennett, James Henry, L.R.C.P.Lond. Beresford, Ralph, L.S.A. The following gentlemen, having previously passed the necessary examinations, and having now attained the legal age of twenty-five years, were admitted Fellows of the College:—

Miles, William Ernest, L.R.C.P. Lond., St. Bartholomew's Hospital; diploma of Membership dated July 30th, 1891.
Clegg, John Gray, M.B., Ch.B. Vict., Owens College and Royal Infirmary, Manchester; Nov. 12th, 1891.

Conjoint Board in England of the Royal Colleges of Physicians and Surgeons.

The following gentlemen, having passed the necessary examinations, have been admitted by the two Colleges Diplomates in Public Health:—

Adams, Ed. Weaver, L.R.C.P.Lond., M.R.C.S.
Bolton, Alfred, L.R.C.P.Lond., M.R C.S.
Brown, R. King, M.B. and B.Ch. R.U.I.
Close, H. A., Deputy-Inspector-General, R.N., L.R.C.P.Lond. M.R.C.S.
Elkington, Henry P. G., Surgeon-Captain, Army, L.R.C.P.Lond
Harris, Frank Drew, L.R.C.P.Lond, M.R.C.S.
Hatch, Herbert L., L.R.C.P Lond., M.R.C.S.
Henderson, James T., L.R.C.P.Lond., M.R.C.S.
Illingworth, C. R., M.D.Ed., M.R.C.S.
Oakeshott, Walter Field, L.R.C.P.Lond., M.R.C.S.
Toogood, F. Sherman, M.D.Lond., M.R.C.S.
Thompson, Wilberforce, L.R.C.P.Lond., M.R.C.S.
Watson, J. Riley, M.B. and C.M.Ed.

Nine candidates were referred for six months.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. Morison's paper on "A Form of Dysphagia associated with Chronic Alcoholism" is marked for early insertion.

F.R.C.S. is thanked for his communication. He will see the subject is referred to in another column.

Dr. G. E. G.—Quite impossible at present.

COST OF CREMATION.

Cheapness is one of the chief arguments advanced in favour of cremation. That quality, however, is by no means an indispensible adjunct, as shown by the cost of the cremation of the late King of Siam. The ceremony, as it has now been officially announced, was carried out at an expense of £99,000. The tendency to extravagant rites, however, has always been a characteristic of Eastern nations. Indeed, long ago summary laws were passed in India forbidding more than a certain sum to be expended in buying costly woods and incense for cremation. In that country, as in ours, an expensive funeral will frequently plunge a family into poverty.

Mr. J. S. T.—A very interesting subject undoubtedly, but more suitable for a lay journal.

FROM GENERATION TO GENERATION.

The unusual circumstance of five generations living in the same village is now existing at Skillington, near Grantham, where there are living Thomas Duffin, who is 97; George Duffin, his son, aged 73; George Duffin, grandson, 48; Joseph Duffin, great grandson, 26; and George Duffin, great-great-grandson, aged 6. The head of the family is still hale and hearty.

Mr. F. E. Perkis, R.N.—The matter shall be considered.

AN OINTMENT THREE THOUSAND YEARS OLD.

Among the Egyptian curiosities contained in the famous museum of the Duke of Northumberland at Alnwick is a jar of ointment which is upwards of three thousand years old. Notwithstanding this extreme antiquity the ointment retains a powerful smell This result, obtained as it was in pre-antiseptic days, says a good deal for the thoroughness of the empirical methods in vogue amongst the early Egyptians. How much of the modern therapeutic output in ointments would stand such a test as the above?

Dr. Chas. Forbes.—Parts II and III have have been received, but the first part has not yet come to hand.

Meetings of Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 21ST.

Epidemiological Society of London (11 Chandos Street, Cavendish Square).—At 8 p.m., Dr Frank Clemow: A Contribution to the Epidemiology of Cholera in Russia.

London Post-Graduate Course.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. Habershon: Demonstration of cases from the Post-mortem Room. Royal London Ophthalmic Hospital, Moorfields.—At 8 p.m., Mr. A. Q. Silcock: Glaucoma. Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Seborrhœa.

West London Hospital (Hammersmith).—At 5 p.m., Dr. William Hunter: Disease of the Blood (with lantern demonstration). (Post-graduate Course.)

THURSDAY, FEBRUARY 22ND.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street.—At 3·30 p.m., Dr. Penrose: Tuberculosis in Children. National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Taylor: Muscular Atrophy. Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Mr. Henry T. Butlin: Cases in the Wards.

Royal College of Physicians of London (Examination Hall, Victoria Embankment).—At 5 p.m., Dr. J. Berry Haycraft: Weismannism Disease and Race Progress. (Milroy Lecture.)

FRIDAY, FEBRUARY 23RD.

Clinical Society of London.—Living Specimens at 8 p.m.:—Dr. Sansom: A case of Aphasia.—Dr. Francis Hawkins: Displacement of Heart in a Child due to Fibroid Phthisis.—Mr. Stanley Boyd: Knee after Rupture of Anterior Crucial Ligament.—Mr Battle: (1) A case of Wiring the Pelvis after Compound Fracture; (2) Reduction of Intractable Dislocation of the Hip by means of Incision of the Joint.—Dr. Harry Campbell: Interstitial Nephritis with Albuminuric Retinitis in a Youth aged Nineteen.—Dr. Arthur Davies: (1) A case of Myxœdema after Thyroid Feeding; (2) Partial Congenital Dislocation of both Clavicles.—Dr. Wilberforce Smith: Large Apical Cavity, Treatment by Carbolic Hat-box Respirator, Cicatrisation.—Mr. Bland Sutton: A case of Excision of part of the Clavicle for Myeloid Sarcoma four years ago.—Dr. Calvert: A case of Hysteria in which the Breathing is almost entirely Diaphragmatic.—Mr. Storer Bennett: A case of Dentigerous Cyst in the Upper Jaw with the tooth in situ. Papers at 9 p.m.:—Dr. Mott: Multiple Toxæmic Neuritis.—Dr. Hale White: Diphtheritic Peripheral Neuritis causing Sudden Death.—Mr. Mansell Moullin: A case of Cerebral Abscess.—Mr. Battle: Three cases of Extra-dural Hæmorrhage.

London Post-Graduate Course.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. R. Douglas Powell: Angina Pectoris.

Royal College of Surgeons, England.—At 5 p.m., Prof. E. T. Collins, The Anatomy and Pathology of the Eye.

SATURDAY, FEBRUARY 24TH.

London Post-Graduate Course.—Bethlem Hospital, at 11 a.m., Dr. Corner: Insanity with Syphilis; Insanity with Organic Brain Disease.

MONDAY, FEBRUARY 26TH.

Royal College of Surgeons, England.—At 5 p.m., Prof. Chas. Stewart's First Lecture on The Physiological Series of Comparative Anatomy in the Museum of the College.

St. John's Hospital for Skin Diseases (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Tuberculosis of the Skin

Vacancies.

Coombe Lying-in Hospital, Dublin.—**Assistant Master.** Applications to the Master. (See advert.).

County Asylum, Rainhill, near Liverpool.—**Assistant Medical Officer** (unmarried). Salary £100 per annum, rising annually, with furnished apartments, board attendance, and washing. Applications and testimonials to the Medical Superintendent.

County Borough of Oldham.—**Medical Officer of Health.** Salary £400 per annum. Applications and testimonials to the Town Clerk by Feb. 26th.

County Lunatic Asylum, Snenton.—**Assistant Medical Officer** (unmarried). Salary £100 per annum, rising £10 annually to £150, with board, lodging, washing, and attendance. Applications and testimonials to the Chairman of the Committee of Visitors on or before Feb 27th.

Manchester Royal Infirmary.—**Resident Medical Officer** of the Convalescent Hospital at Cheadle (unmarried). Salary £150 per annum, with board and residence. Applications and testimonials to the Chairman of the Board by 3rd March.

National Orthopædic Hospital, London.—**Assistant Surgeon.** Must be a F.R.C.S. Eng. Applications to the Secretary. (See advert.).

Paddington.—**Medical Officer of Health.** Salary £600 per annum. Applications and testimonials to the Vestry Clerk on or before Feb. 26th.

Sheffield Public Hospital and Dispensary.—**Senior House Surgeon** (unmarried). Salary £100 per annum, with board, lodging, and washing. Applications and testimonials to Hon. Sec. Med. Staff, by Feb. 26th.

Tiverton Infirmary and Dispensary.—**House Surgeon and Dispenser** (unmarried). Salary £100 per annum, with lodgings, attendance, &c. Applications and testimonials to the Secretary on or before Feb. 23rd.

Appointments

Bredin, J. N., L.R.C.S.I., L.K.Q.C.P.I., L.S.A., Medical Officer to the Staff, Great Eastern Hotel, Liverpool Street.

Carey, C., L.R.C.P.Edin., L.M., M.R.C.S., Medical Officer of the Cottage Hospital, Bromsgrove.

Coombe, C. F., L.R.C.P.Edin., M.R.C.S., Honorary Medical Officer to the Children's Hospital, Sheffield.

Dodsworth, F. C., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for Chiswick, Middlesex.

Griffiths, H. J., M.B., B.S.Lond., M.R.C.S., L.R.C.P.Eng., Second Assistant Medical Officer to the Greenwich Union Infirmary.

Hale, E. T., L.R.C.P., L.R.C.S., L.M.Edin., Medical Officer for the Fourth Sanitary District of the Bedminster Union.

Lee, C. G., M.R.C.S.Eng., Honorary Aural Surgeon to the Royal Southern Hospital, Liverpool.

Mackintosh, A., M.D.Glasg., L.F.P.S., L.M., Medical Officer of Health to the Clay Cross Local Board.

Niven, J., M.B.Camb., B.C., Medical Officer of Health of the City of Manchester.

Pearce, A., M.R.C.S., Medical Officer of Health of the Kingsbridge and Salcombe Port.

Quarry, M. H., M.B., B.Ch.Irel., Assistant Medical Officer to the Lambeth Infirmary.

Robertson, J. H., M.B., M.S.Edin., Medical Officer of Health for the Byhope and Tunstall Sanitary District.

Sawyer, J. A. F., L.R.C.P., L.R.C.S.Irel., Medical Officer of Health for Clevedon.

Thomas, A. W., L.R.C.P., L.M., L.R.C.S.Edin., Medical Officer of Health for the Swaffham Urban Sanitary District.

Underhill, T. G., M.D.Edin., F.R.C.S., Medical Officer to the Cottage Hospital, Bromsgrove.

Willson, A., L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer to the City Hospitals, Sheffield.

Young, J., L.R.C.P.Lond., M.R.C.S., a District Medical Officer to the St. George Local Board, Bristol.

Marriages.

Wheatley—Bowring.—Feb. 19th, at St. Mary's Church, West Kensington, Arthur W. Wheatley, M.B., of Kensington, to Alice, widow of John F. Bowring, of Kingsbridge, Devon.

Deaths.

Collot.—Feb. 11th, at Malta, James Alexander Collot, Staff-Surgeon H.M.S. Collingwood, aged 44.

Dowling.—Feb. 10th, at the residence of his uncle, Stephen F. Dowling, J.P., Limerick, Dr. Edmund J. Dowling, late of Manchester, aged 41.

Greensil.—Feb. 17th, at Martley, near Worcester, John Nicholas Greensil, M.R.C.S., aged 74.

Peppin.—Feb. 13th, at Ivy Bank, Weymouth, Henry Cole Peppin, M.R.C.S., late Army Surgeon-Major.

Watson.—Feb. 9th, at the Tower of London, James Watson, F.R.C.S., Brigade-Surgeon Army Medical Staff, Retired, aged 57.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

The Lettsomian Lectures

ON

PERITONITIS. (a)

By FREDERICK TREVES, F.R.C.S.,

Surgeon to and Lecturer on Surgery at the London Hospital; Examiner in Surgery University of Cambridge.

LECTURE III—(*Abstract*).

THE general symptoms of peritonitis are so well known, and have been so precisely described, that they call for no special consideration in the present lectures. It will be necessary only to deal with the characteristics of certain individual symptoms, and to define the clinical peculiarities of certain varieties of peritoneal inflammation.

(1) *The nervous phenomena.*—The lecturer proceeded to explain the general arrangement of the nerve supply of the parietes of the abdomen and of the abdominal viscera, which he remarked was somewhat peculiar. The skin over the greater part of the abdomen, over that part at least beneath which lie the chief viscera, is supplied by the lower seven dorsal or intercostal nerves. The same nerves supply the muscles of the belly, viz., the rectus, the two oblique muscles and the transversalis; these identical nerves take a most important part in the nerve supply of the abdominal viscera and of the peritoneum.

It thus happens that an arrangement exists for the most rapid possible conduction of reflex impulses. A cold hand is laid upon the abdomen, or a blow upon the part is threatened, and the muscles of the belly wall become rigid in a moment, or it may be that there is some sudden lesion of the peritoneum or of one of the abdominal viscera, and at once the muscles of the belly wall contract, and a more or less marked hyperæsthesia of the skin develops, and there is thus provided, by the tender integument and by the rigid muscles, that protection and that securing of rest which are the first elements in the natural treatment of a damaged part. Absolute rigidity of the belly, a limitation of the abdominal respiratory movements, and a tenderness of the surface are among the very earliest symptoms of acute trouble within the abdomen.

As peritonitis advances, both the hyperæsthesia of the skin and the contraction of the belly wall lessen and may almost entirely pass away. As the muscles yield, the phenomena of meteorism usually appear, and any tenseness of the abdomen which remains, depends upon flatulent distension of the intestines. As soon as general septic symptoms become marked, both the contraction and the tenderness usually disappear. I have seen two cases of septic peritonitis due to trouble in the appendix, run their entire course with a flaccid belly wall, and with scarcely any tenderness. Both patients were men over 50, no morphia had been administered, and death took place from toxæmia within seven days in both instances. One man spent some hours in applying massage to his own abdomen, and the other drew frequent attention to the absence of tenderness by slapping the abdominal wall.

That pain which the patient feels to be actually situated within the abdomen has the peculiarity that it is not as a rule to be localised at first, but is commonly referred to the great abdominal nerve centres. In the early stages of strangulated hernia or of perityphlitis, for example, the patient very often refers the pain to the region above the umbilicus, and will sometimes place his hand or his finger exactly over the site of the solar or superior mesenteric plexus. I have known the pain in perityphlitis to be referred at first to the opposite or sound side. As symptoms progress the localisation of the pain becomes usually more and more precise, assuming that the trouble still remains, to a certain extent, local. A patient who has had many attacks of perityphlitis gives a very hazy account of the situation of the pain in the first outbreak, but as time advances he often puts his finger directly over the diseased appendix. I have noticed the same phenomenon in intestinal troubles due to limited adhesions. The pain may be at first "all over," or be referred to the median line a little above the umbilicus. In due course, however, it becomes more and more accurately described. (a)

In the symptoms which are associated with an actually advanced peritonitis it is quite evident that the nervous system plays a prominent part. A study of intestinal neuroses makes it easy to appreciate how important that part may be. Not only may colic and diarrhœa occur in instances in which there is no reason to suspect any actual intestinal lesion, but there are cases, more or less clearly proved to be neurotic, in which there were meteorism, fæculent vomiting, and even some signs of strangulation.

A rigor does not often mark the commencement of peritonitis. Among the hundred cases this symptom was recorded in thirteen instances. In two of these the peritonitis had started in the appendix, in one it followed laparotomy, and in ten it had its origin in the pelvis. Of the thirteen patients ten died.

(2) *Meteorism.*—The degree of meteorism met with in peritonitis varies considerably, and is influenced by conditions which are not yet fully understood. When it exists its appearance is coincident with that relaxation of the abdominal muscles to which allusion has already been made. Meteorism may be absent throughout the whole progress of the case, and examples of this are not uncommon in instances of septic intoxication attended with symptoms of a low type. It is most marked in peritonitis attended by actual intestinal obstruction, in examples of perforation, in cases in which there is thrombosis of the mesenteric vessels, and also in instances in which opium has been freely administered. It appears to present no definable relation to the amount or degree of the vomiting. In experiments in which artificial distension of the gut has been brought about, not only do all intestinal movements cease, but peristalsis cannot be induced by any of the usual irritants.

(3) *Vomiting.*—It has been many times remarked that there is no single distinctive sign of peritonitis. Could one single symptom be selected as the one more usually present in all cases of peritonitis, it would probably be vomiting. In the hundred hospital cases vomiting is noted as very slight in as many as 23 per cent. of the examples. In some of these it is described as absent. This may be to some extent explained by the strict rules of dieting which are now more rigorously insisted upon at the present day, and by the fact that a dresser or a nurse may not record the symptom unless the vomiting be copious or very distressing. By very slight vomit is implied vomiting in which the amount actually brought up is trifling. Compared with the sickness attending intestinal obstruction the vomiting in peritonitis generally may be spoken of as always slight. In a very large proportion of the cases which are carefully treated the patient will merely bring up a mouthful of fluid now and then. This is often accomplished with little effort, and many hours may elapse between the successive attacks. What is alarming and distressing in this slight degree of sickness are its persistence and the evil prognosis it suggests. The patient may be apparently improving but there remains this periodical rejection of an ounce or so of fluid, which shows that the improvement is entirely delusive.

(a) Delivered on Feb. 26th before the Medical Society of London.

(a) See some cases by Launstein. *Archiv. fur klin. Chir.*, 1892, p. 120

In some of the more insidious septic cases, and in such examples of peritonitis as occur in the aged or in the subjects of advanced visceral disease, the vomiting often amounts to little more than a slight irritability of the stomach.

In the cases of peritonitis following upon strangulated hernia the vomiting is for the most part very marked and often copious, but it bears no constant relation either to the state of the gut, the degree of peritonitis, or the height of the fever. In perforative peritonitis all symptoms are usually acute and pronounced. There is intense pain and a corresponding degree of collapse, and in the larger proportion of the cases vomiting is conspicuous. It is usually absent in examples of perforation of the stomach. In the cases connected with typhoid fever the relation between the vomiting and the action of the bowels is notable. If all action of the bowel cease, then the vomiting tends to be marked; but if the loose motions are continued, then the sickness is for the most part slight. In the most rapid forms of perforative peritonitis an actual inflammation of the serous membrane plays but little part. Death is from shock or acute general toxæmia.

In cases of peritonitis depending upon disease of the intestine, including mischief in the appendix, vomiting is not, as a rule, a pronounced symptom. In the cases of perityphlitis it is to be noted that it is least marked, as a rule, in the cases in which the bowels act with more or less regularity. In peritonitis taking its origin from the pelvic viscera or parietes, vomiting is seldom very distressing. In the acute cases the symptoms are rather those of septicæmia, and in the chronic cases the disturbance has a great disposition to remain localised. In peritonitis following upon operation or accidental wounds vomiting is rarely absent. It may not be marked, and may consist merely of an irritability of the stomach, but there it remains—a symptom which gives the greatest anxiety to the surgeon, and which no treatment appears capable of controlling. It may not be complained of by the patient, but as already said its gravity does not depend upon either its frequency or the amount ejected, but upon its deadly persistence.

(4) *Constipation.*—Cessation in the action of the bowels is a conspicuous feature in peritonitis. The morphia which is often so very freely administered in this affection probably takes some share in the production of this symptom.

In the 100 cases of peritonitis from the London Hospital the bowels are classed "loose" in twenty-eight instances. In some of these twenty-eight cases there was actual diarrhœa, in others the bowels acted with frequency and without artificial aid, while in a third series of cases a free action was maintained by enemata or by aperients.

(5) *Lung complications.*—In dealing with this feature of peritonitis, mere congestion of the lungs and a slight degree of bronchitis have been disregarded. Among the 100 cases, there were no less than seventeen in which pleurisy or pneumonia appeared after the peritonitis set in. In the examples of peritonitis of intestinal origin, there were seven cases, viz., two of right pneumonia, one of left, one of right pleurisy, one of left, and two of right pneumonia with double pleurisy. Five out of the seven cases were in instances of peritonitis associated with hernia or perforation. In the examples of peritonitis starting from the pelvic organs, or from sources outside the abdomen, there were ten cases, viz., one of double pneumonia, two of right pleurisy, five of left pleurisy, and two of double pleurisy. In six of the instances the peritonitis had commenced in the pelvis—a notable fact—and in the remaining four it was due to a wound of the abdominal wall.

(6) *Fever.*—The temperature in peritonitis is liable to fluctuations so numerous and extreme that it is difficult, if not impossible, to deduce any type of temperature which may be considered to be characteristic of the disease. Probably there is no affection attended with fever in which the temperature charts of a long series of cases exhibit fewer data for the establishment of a common standard of fever.

A careful examination and analysis of the temperatures recorded in the 100 cases from the London Hospital makes it evident that the one symptom of fever can afford very little guide in estimating the gravity of the case or in forming a dogmatic prognosis. A comparison of the temperature charts in the cases that recover with those that die leads only to a bewildering result. In some of the fatal cases the temperature has moved steadily upwards, in others it has moved steadily downwards, in the third series of cases an even line of high fever has been followed, while in a fourth set of instances the temperature has been about or below normal It is quite evident that no marked or regular relation exists between the range of temperature and the character of the peritoneal effusion.

In very general terms it may be said that perforation leads at first to a sudden drop in temperature, and that if the body heat be at the time high the onset of diarrhœa is associated with a more or less rapid diminution of fever. Moreover, it may be remarked that the chart record which carries with it the stamp of an almost inevitably fatal result is that in which the temperature is for consecutive days below normal.

The Treatment of Peritonitis.

In considering the treatment of any grave affection, it is well to recollect that certain of the so-called symptoms of a disease are not crass evidences of a disturbing evil within the body, but are rather the natural expression on the part of the organism of an attempt to rid itself of a trouble. Many symptoms are, in fact, curative acts, and are the measures of a natural treatment, and not the mere purposeless signs of an unnatural disturbance.

In peritonitis the exhaustion, the rigidity of the belly wall, the pain, the vomiting, and the not infrequent sense that the bowel needs to be emptied of flatus, would suggest the recommendation of absolute rest, of attempts to relieve pain, of starvation, and, under certain circumstances, of means to relieve the intestine. If, in contemplating a patient with peritonitis, one could regard his more conspicuous symptoms as natural attempts to afford relief, they would appear to be in the direction of securing quiet within the enclosure of the abdomen, and of effecting an evacuation of the alimentary canal.

In the account which follows of the treatment of peritonitis, this suggestion from the therapeutics of nature is not disregarded.

(1) *Rest.*—Absolute rest in the recumbent position appears to be the first obvious indication. The knees may be flexed over a pillow to lessen the tension on the abdominal walls, and to favour the patient's instinct to assume that posture. The upper part of the chest and the ever restless upper limbs should be protected by a woollen jacket, and no reasonable restraint offered to the patient's inclination to hold the hands above the head. This favourite posture, by acting upon the lower part of the thoracic wall, assists also in diminishing the tension within the abdomen. It is cruel to insist that the hands should be kept beneath the bedclothes. The state of misery in peritonitis is acute enough without being increased by purposeless and rigid formulæ. Cold hands do not cause death, but as on exposure they tend to become cold, they should be covered up. The wretchedness of restlessness has a natural relief in little movements.

(2) *Feeding.*—The old rule of eighty years ago of giving as little food as possible by the mouth cannot be improved upon. The stomach is not in a condition to receive nourishment, and what is taken usually remains unutilised, and is returned unchanged. The practice sometimes met with of laboriously plying the patient with teaspoonfuls of this meat extract or of that, recalls the legend of the Daaïdes, who spent their energies in pouring water into pitchers without bottoms.

In the matter of feeding there are two extremes to be avoided. The first is the rigid, unreasoning, and often needlessly cruel prohibition of any kind of food by the mouth, and the second is the reckless and intemperate use of ice, or iced fluids.

Thirst is often a most terrible symptom in peritonitis. It is not always quite relieved—at first, at least—by rectal injections. The patient is ready to give his life for a drop of cold water. If he takes it he is sick, but he is much relieved. This little indulgence does not introduce anew the symptoms of vomiting. It is there, but it is latent, and the drop of cold water only makes it evident. The patient will not die of vomiting, and simply because a rigid exclusion of all fluid by the mouth does not render the symptom apparent it does not render it non-existing. The man would sooner vomit than endure this thirst. Very often great relief is given by allowing a fairly copious draught of fluid, which is soon rejected, and which—as it were, by washing out the stomach—leaves the patient for a while infinitely comforted. On the other hand, the perpetual sucking of ice is as bad as the perpetual teaspoonful of useless jelly of decomposible meat juice. The filling of the stomach with iced water does undoubtedly add to the general depression of the patient, especially when vomiting has been brought into abeyance by morphia.

The right course appears to lie between these two extremes. There should be no rigid formula except this—let the patient take as little food as possible by the mouth. If there be a raging thirst, let him have a little ice—and very little suffices—or a little iced milk and soda water, or if, as is common, the inclination lies to something warm, let him take a few spoonfuls of hot water or of weak tea made hot, or of beef-tea at a like temperature. It is not the nourishment that is needed (and I imagine that the nourishment in beef-tea is merely an ancient but cherished fiction), but some fluid in the stomach.

It is better within reasonable limits to be guided by the patient's own instincts than by a blind formula founded upon a doubtful physiology.

(3) *Opium.*—Here again, the old practice appears to be the best. Give as little opium as possible. In the early stages of acute peritonitis, and especially in the perforative forms, and in those depending upon appendix troubles, morphia in the form of a hypodermic is absolutely necessary. In the worst instances, it may certainly avert death from shock. Under its influence the patient revives, and the more intense symptoms become greatly modified. Morphia should never become a feature in the routine care of peritonitis. It masks the symptoms, hinders the natural process of cure, and hampers treatment. The indication for it is actual pain, and not mere restlessness and misery. In the really septic forms, but very little morphia is called for, and often none at all. Its evil effect in the after treatment of cases of abdominal section has been amply demonstrated. In quite hopeless cases, there can be no objection to its freer employment, but in other instances the administration and the dose of the drug must be sanctioned and measured by the one symptom, pain.

(4) *Aperients.*—At the commencement of the century the use of aperients was a necessary element in the routine treatment of peritonitis. By aperient treatment may be understood the obtaining of an action of the bowels by either drugs or enemata. After a certain number of years the practice altered, and the dictum went forth that when any signs of peritonitis were present, aperients were to be absolutely forbidden.

Within the last few years the more ancient method has been revived, but it has been revived with very radical modifications. To Mr. Lawson Tait the profession is indebted for this return to an almost forgotten practice, and above all, for the employment of that practice with the new element of discrimination. Mr. Tait's measure has been frequently spoken of as "the treatment of peritonitis by aperients," and it has been assumed by some—and probably with disaster—that a purgative is necessary in every case of peritoneal inflammation. Mr. Tait's precise words on this subject are as follows :—"I have never said that the purgative treatment will cure peritonitis, for peritonitis, once it is completely established, is a practically incurable disease, and almost uniformly fatal." (*a*)

It is on this very point that the centre of the position with regard to this treatment turns. Aperients can never be adopted in the routine treatment of peritonitis. In the larger proportion of cases this measure is entirely useless, and in the great series of the septic forms it is more or less impracticable.

It is a fact that the most successful treatment of acute obstruction of a certain grade is that which provides for a thorough evacuation of the loaded gut. A blindly executed enterostomy, with an utter ignoring of the cause of the obstruction, has been attended by better results than have operations in which the agent of the obstruction has been discovered, after elaborate search, and has been satisfactorily dealt with. This treatment of acute obstruction by the evacuation of the bowel before all things, we owe to Benjamin Travers, the father of intestinal surgery. In cases of strangulation of a certain degree he insisted that the bowel should be cut into and emptied, even after the obstructing band had been removed. He considered that the operation was not complete until this had been done ; he urged that safety was only to be obtained by an evacuation of the gut, and he supported his views by numerous cases and experiments.

Another illustration of these selfsame points is afforded by perityphlitis. In a previous section of these lectures I have shown that those cases of perityphlitis, in which there is diarrhœa, or in which the bowels act naturally or under the influence of aperients, are attended with a much lower mortality than are the cases in which constipation is marked. In my own experience I am convinced of the value of the aperient treatment in the earliest stages of these cases, and of the pursuit of the same measure throughout in selected instances. In some cases, however, nothing within reason will bring about an action of the bowels. When once general peritonitis has established itself, an aperient is without avail.

(5) *Blood-letting.*—This measure of treatment may with advantage be more extensively employed. It is no longer likely to be used in the unreasoning and mechanical fashion of bygone days. In robust forms of localised peritonitis, blood-letting is attended with admirable results. In perityphlitis the application of half-a-dozen leeches often acts with magical effect. In the older accounts of the treatment of peritonitis by bleeding, no good appears to have followed in cases in which the inflammation was diffused, except, perhaps, in some examples due to injury. On theoretical grounds this is precisely what would be expected.

(6) *Operative measures* (*a*).—These are represented by incision and drainage, with or without irrigation. This treatment must be considered as it applies to peritonitis, under two entirely different aspects. In one series of cases there is vigorous well-defined inflammation, the local symptoms are marked, pus is produced, and may be considerable in amount, and the exudation is more or less clearly localised.

In the other series of cases, the peritonitis is diffused, the constitutional symptoms are more prominent than the local ones, the changes in the serous membrane—so far as evidence of inflammation is concerned—are comparatively slight, and are out of proportion to the general disturbance.

In the first series of cases surgical interference by incision and drainage ranks with the procedure of evacuating a large abscess.

In the second series the cut into the abdomen and the subsequent flushing out or drainage, are to be compared with the washing out of the stomach after an active poison has been swallowed.

The operative treatment of suppurative peritonitis, especially when the effusion is localised, has been remarkably successful. Records of the operation extend back into the eighteenth century, and all that modern surgery can lay claim to is the application of the treatment with greater boldness, with greater frequency and with infinitely less delay.

The operative treatment of general diffused non-tuberculous peritonitis has, so far, no record to boast of, and little progress to chronicle. I am doubtful if a single human life has been saved by surgical interference in a genuine case of peritoneal toxæmia. Surgical treatment has been most discouraging in acute peritonitis following upon gangrenous hernia, upon operation, and upon puerperal infection. It has met with but little better results in cases of perforation, in which the serous inflammation has been well established.

As to the actual mode of operating adapted for the different varieties of peritonitis, I would venture to draw attention to the following points. In all cases it is to be assumed that the skin over the operation area is cleansed and prepared in a suitable way, and that the surgeon adopts those measures which students, in their examination papers, are so fond of describing as "strict antiseptic precautions."

In cases of localised purulent peritonitis an incision should be made into the collection by the most direct

---

(*a*) The treatment of tuberculous peritonitis is not considered.

route. When the pus has escaped, a rubber drainage tube of suitable size and with stiff fenestrated walls should be passed to the bottom of the cavity. A dressing of some absorbent material, such as Tillmann's papers, sal alembroth or cyanide gauze is then applied. I have seen no advantage attend either the fuller evacuation of the pus by squeezing, or the immediate irrigation of the cavity, and I am confident that distinct harm may be done by scraping the wall of the enclosure, by persistent searching for a diseased appendix or other cause of the trouble, and by stuffing the exposed space with a considerable quantity of gauze.

At the end of twenty-four or thirty-six hours the irrigation of the cavity may be commenced and continued twice daily, and now and then a little iodoform emulsion may be introduced.

In some examples of perityphlitis a well encapsuled collection of pus is not exposed, but the knife enters into an ill-defined district containing a variable quantity of thin, greenish, and often offensive matter, which appears to saturate the tissues. In such circumstances I have been in the habit of using a drain composed of strips of iodoform gauze, which are carefully introduced into the lowest accessible recesses of the region.

In cases of generalised peritonitis the procedure adopted must obviously depend upon the cause and degree of the trouble. If the exudation be serous it will suffice if the fluid be evacuated, if the peritoneal cavity be gently dried in its most dependent parts by means of gauze sponges, and if the abdomen be closed without drainage.

When the exudation is sero-purulent or purulent it is in many cases desirable that the cavity be irrigated. The fluid which appears to be best suited for this purpose is a ·6 per cent. salt solution made warm. After the washing the depths of the peritoneal cavity are dried, so far as is possible, with sponges, iodoform powder is very freely dusted over the portion of the serous membrane most involved, a long, rubber, fenestrated drainage tube is introduced and the abdominal wound is closed. Any treatment directed against the cause of the peritonitis will be independent of these measures.

There are cases in which the peritonitis is more plastic in character. The intestines are found to be matted together with greyish lymph, which may be present in considerable quantity. The breaking down of these adhesions causes no little amount of bleeding, and such a step is evidently destructive of a certain desirable process of repair. Still, in order to search for the cause of the peritonitis, assuming such search to be indicated, and to set free an amount of exudation which is imprisoned between the attached coils, this freeing of adhesions must be at a certain, very limited extent carried out. There will probably be a sero-purulent exudation in the belly cavity, and the gentlest movements of the fingers among the recently attached intestines will set free more fluid, which will be probably less opaque. A clump of adherent intestines will often cover and protect a perforation, and the ubiquitous fingers will many times close such an opening with more speed and security than are provided by any system of suturing.

As the surgeon, therefore, reaches what appears to be the starting point of the peritonitis he must proceed with the utmost caution, and be not only prepared. but rather inclined to leave the actual *Fons et origo mali* undemonstrated. The main purpose of the operation is to allow a noxious exudation to escape, and, if possible, to free the peritoneum of the cause of its trouble. In the class of case now under discussion, a perforation will be very often the starting point of the peritonitis; the lapse of time and the plastic character of the inflammation afford evidence that the perforation is, for the time being closed. If the operator can rid the serous cavity of the effects of the perforation, he may often leave the breach itself to be dealt with by natural means. The wisdom of doing no more than is necessary, or as little as is obvious, is well illustrated by these cases.

Irrigation.—Mere blood is better removed from the peritoneal cavity by sponging, than by irrigation. If the operation area be well circumscribed by sponges, if the shoulders be raised so that blood will reach the more dependent tracts, and if a sponge be introduced into the pelvis at an early stage of the procedure, there is little trouble with blood clot. Coagulated blood is certainly very much more easily and certainly removed by means of gauze sponges, than by a stream of water. The same observations apply to what may be termed healthy cyst contents, to fluid from hydatids, to bile, and to matter escaping from the stomach or intestine. With careful plugging and a watchful use of sponges a wide-spread extravasation is uncommon.

If it does take place the gauze can usually reach it. Irrigation would possibly have the effect of spreading the noxious fluid—as for example intestinal matters—over a still wider area. It may be said, therefore, that if certain precautions be taken, the cleansing of the peritoneal sac may be best and most safely accomplished by dry sponging.

If there be a considerable outpouring of such a material as putrid pus, or if there be a copious escape of gut contents, as from the giving way of a distended bowel above a point of obstruction, then it may be better that the whole peritoneal cavity be irrigated. In such a case the amount of the extravasated fluid and its wide distribution would render its complete removal by sponging difficult.

This irrigation is best conducted by the following means. The fluid used is a sterile ·6 per cent. salt solution at blood heat. It is introduced at low pressure but in a wide stream. The irrigating tube is of soft rubber and may have a diameter of three-quarters of an inch. The tube itself is introduced into the belly cavity. The flow through it can be regulated by a clip. Any form of rigid nozzle is to be most strongly condemned. The solution should flow gently into the abdomen. The peritoneal cavity is to be flooded and not to be scoured out with a violent stream of water, which hisses and rushes from a vulcanite nozzle as from a miniature fire-hose.

When the belly cavity is quite full of fluid the surgeon's hand—which is already in position—is moved to and from among the intestines with great gentleness. The coils of bowel are thus rinsed. By a movement of the hand and by pressure here and there the fluid overflows from the wound and is replaced by the steady stream.

As the water which escapes becomes clear the upper end of the operation table is raised, so that the shoulders are much elevated, and then little has to be done but to wash out the most dependent parts, including especially the pelvis, and to allow the upper parts to drain. Finally, what fluid remains in the pelvis is removed with sponges, and a sponge in a holder is retained in the bottom of the pelvis during the introduction of the stitches and only withdrawn at the last moment.

Drainage.—It will be allowed by most that drainage is necessary, when either an actually noxious material is left in the peritoneal cavity, or when it is assumed that an extensive effusion will follow upon the laparotomy. Considerable differences of opinion must exist as to what constitutes, either in substance or in amount, a noxious material, and also to what extent a possible effusion is to be met by drainage.

A stout rubber drainage tube of large size and well fenestrated, passed into the midst of the area which is the most disturbed, appears in most cases to answer all reasonable purposes. It is not suited for most tuberculous cases. It must be assumed that the surgeon has no objection after the operation to frequent, and perhaps extensive, changes in the patient's position, for the purpose of assisting the process of drainage. I have myself seen no harm arise from a liberal fulfilment of this object. In certain instances, some of which I have already indicated —a gauze drain appears to be better adapted for the case than a rubber one. This drain is simply composed of a long strand of iodoform gauze about one and a half inches wide, and some five to six layers thick. It appears to have been first advocated by Bardenheuer. In a case of purulent peritonitis, Jalaguier (a) has passed these strands of gauze in all directions among the intestinal coils from the diaphragm to the pelvis with good result.

A like proceeding in like cases is advocated by Steinthal. (b)

The great objections to the iodoform drains are these. They may induce symptoms of poisoning if very extensively employed, they are most difficult to remove unless there be a free discharge, and their use is apt to be followed by ventral hernia.

(a) *Bull. et Mém. de Soc. de Chir.*, 1891, p. 800.

(b) German Surgical Congress, 1888.

Some surgeons, either to supplement or to replace drainage, allow the wound to gape, or support it merely by a few quite loose sutures. (*a*) This measure has been especially advocated in the treatment of perforative or purulent peritonitis.

In conclusion, it only remains to be said that the surgical treatment of peritonitis has not yet reached a position which is either satisfactory or secure. There has been no lack of boldness in the measures used, and little sense of discouragement at the results obtained. Surgical enterprise has been directed against effects and against damage done, rather than against causes and the beginnings of evil. The surgeon holds the same position in regard to peritonitis which was held some thirty years ago in regard to wounds and more accessible forms of inflammation. At that time he dealt only with the consequences of pathological wrong-doing, just as now he concerns himself with the prevention of troubles which he has learnt to control. Peritonitis will be more successfully treated when measures can be directed against the sowing of the wind rather than, as now, against the curbing of the whirlwind.

Post-Graduate Lectures.

SEA VOYAGES IN CATARRHAL PHTHISIS. (*b*)

By E. SYMES THOMPSON, M.D., F.R.C.P.Lond.,

Consulting Physician to the Hospital for Diseases of the Chest, Brompton; Gresham Professor of Medicine.

THE term "catarrhal phthisis" is a clinical, rather than a pathological, one, and is used as the subject of this lecture because it corresponds to a fairly definite group of cases, examples of which are met with in practice every day.

There is a large number of individuals in whom an ordinary catarrh does not confine itself to the nasal and pharyngeal mucous membrane, but extends into the trachea and larger bronchi. These form one set of cases in which catarrhal phthisis occurs. A second set is furnished by those diseases, of which measles and influenza are the most important, and by far the most characteristic, which are normally accompanied by an inflammation of the bronchi that has of itself a tendency to advance towards the smaller bronchi, the bronchioles, and even the pulmonary alveoli. The third set corresponds to those cases in which tubercular disease is laid down on some acute pneumonia which has not undergone proper resolution. Three types will, therefore, be considered: the ordinary, that affecting the large bronchi; second, the broncho-pneumonic, affecting the small bronchi and alveoli; and third, the acute pneumonic, in which a whole lobe has at some previous time been affected with some non-tubercular but specific poison. Of these the second or broncho-pneumonic is by far the most common and important. (All three types were presented for examination at the end of the lecture).

At the outset, a question of great difficulty presents itself, and it is that of deciding whether the types above mentioned are primarily tubercular or primarily non-tubercular. No doubt catarrhal phthisis generally occurs in those having a hereditary tendency to the disease, but really so few persons have absolutely no tubercular family history that too much stress must not be laid on this point. My own personal opinion is that a very considerable proportion of cases of catarrhal phthisis are at the commencement non-tubercular, but that the irritative and inflammatory pulmonary conditions, for example, of measles, though they may at first be transient, especially if care be taken, may, in the absence of proper precautions, become chronic, impairing the vitality of the lung tissue and forming a preliminary stage which prepares the ground for the reception and growth of the tubercle bacilli. That this is further aided by the extension of the catarrhal process to the deeper ramifications of the bronchial tree, and particularly to the alveoli, is only what must be expected if we bear in mind the delicacy of the alveolar walls and the readiness with which their vitality may be impaired, and the lengthened period during which the catarrhal products must remain in the ultimate portions of the lungs.

Another disease similar in its action to measles is influenza, and at the present time a large number of cases of basal tuberculosis are dating their origin from the epidemics of 1890, 1891, 1892, and 1893. The broncho-pneumonia that so commonly accompanied an attack was in itself comparatively harmless, and provided the patient took proper care and did not run the risk of accentuating the lung-condition by an undue exposure during the early days and weeks after his attack, as a rule, he recovered completely. But this care was neglected in many cases, and the effect has been to impair the vitality of many lungs, and to cause the deposition and growth of tubercle bacilli.

The catarrhal products of broncho-pneumonia have a natural tendency to dry up or become cheesy, or perhaps chalky, and this very alteration is in favour of their subsequent tubercular modification. Hamilton attributed the well-known comparative immunity of the subjects of mitral disease to phthisis to the fact that the œdematous fluid that in that disease collects in the lung prevents the broncho-pneumonic exudations from becoming cheesy or chalky, and assists their expectoration. We shall later see that this fact has an important bearing upon the climatic treatment of individual cases.

Such is the class of tubercular disease that I wish to put before you to-day.

One chief consideration, is the climatic treatment, and to that I will now briefly direct your attention. Speaking generally, the climatic treatment of phthisis is of two kinds: (1) That of moist and warm air, as represented by a sea voyage. (2) That of dry, cold, and high altitudes, as, for example, The Engadine. In many cases the two can best be used in conjunction. Much of the benefit derived from a residence in the high table-land of South Africa depends upon the sea voyage which has been undertaken before proceeding to the high land. It is an advantage to a person with catarrhal phthisis to pass through tropical oceanic regions where the air is highly charged with moisture, and where consequently the catarrhal products in the lungs are softened and moistened before going to the high table-land where the increased expansion of the lungs and the improved physical powers will serve to expel these products. The second part of the treatment is rendered easier by the first. Moreover, excesssive dryness of the air, such as occurs in Davos during the winter months, when all the moisture of the air has been frozen and deposited, is of itself a disadvantage. Such air irritates the mucous membrane, and although the cool outdoor air after first emerging acts as a sedative, the drier atmosphere within the house (which of necessity must be artificially warmed, and further, deprived of moisture) often excites unnecessary coughing. Consequently, in recommending high cold climates for catarrhal phthisis this natural condition must be borne in mind, and the cough should be the leading criterion, for although limited alveolar catarrh is undoubtedly benefited by mountain air the Alps may act prejudiciously on the case in other respects.

Another important point wherein oceanic life is beneficial is that common catarrh is so rarely contracted at sea; the micro-organism of catarrh, if one exists, as

(*b*) Abstract of lecture delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.

seems highly probable, inhabits the neighbourhood of land. Many a delicate passenger has been absolutely free from catarrh though exposed to winds and wet from all quarters in mid-ocean, but becomes attacked directly the ship enters the Channel. On the other hand the high altitudes are extremely valuable on account of the large amount of sunshine that is there obtainable. It is known that the tubercle bacillus grows in inverse proportion to the amount of light, and that in bright sunshine it will not grow at all. The active rays of the sun are vastly different in power in various parts of the world, and photographers tell us that plates that must be exposed in England for more than five minutes, require no longer than one minute at an elevation of 5,000 feet. It is very probable, therefore, that the sunshine has some special and, as yet, unrecognised power in the treatment of phthisis at high altitudes. In the next place the comparative absence of putrefaction-bacteria as a result particularly of the low temperatures in high lands is of itself of extreme importance, for the most evident symptoms of tuberculosis are those of the suppurative processes that supervene in the necrotic areas produced by the growth of the tubercle bacillus. Do away with these putrefaction-bacteria and the hectic symptoms disappear, and the chances of recovery are definitely increased.

In a word then, in catarrhal phthisis the indication is a moist warm climate, such as that afforded by a course of treatment at Mont-Dore, or a sea voyage if the secretion be slight and if the sounds in the chest be sticky, to be followed a short time after by residence in a dry sunshiny atmosphere at a high altitude ; whereas if the catarrh be recent and the secretion be not inclined to become inspissated this first part of the treatment may be dispensed with, and such places as Davos, St. Moritz, or the Karoo, may immediately be sought.

THE

SANITATION OF PLACES WHERE FOOD IS STORED AND PREPARED. (a)

(A) BAKEHOUSES.
(B) KITCHENS OF RESTAURANTS.

By F. J. WALDO, M.A., M.D. (Cantab.),
Diplomate in Public Health, Royal Colleges of Physicians and Surgeons, London ; Medical Officer of Health, St. George-the-Martyr, Southwark, Inner Temple and Middle Temple.

Mr. Chairman, Ladies, and Gentlemen,—The subject upon which I have been invited to address you covers so much ground that it would be hopeless to attempt to deal with it exhaustively within the limits of time allotted to this paper. I therefore propose to confine my remarks more particularly to the consideration of the hygienic aspects of bakehouses. At the same time it may be broadly stated that many of the objectionable features met with in ill-regulated bakehouses are reproduced in bad kitchens.

After a prolonged consideration of this question, I have been forced to the conclusion that throughout the United Kingdom there is urgent need for inquiry and reform. Under the present system the health of the workman often suffers, and in some instances the public health is also endangered. To remedy these evils I would suggest (1) that inspection under existing statutes should be more systematic and complete ; (2) that legislation is needed to extend the powers of local authorities to deal with all aspects of the bakehouse question. Further, I am of opinion that a proper scheme of legislative action could be best initiated by a Select Committee of the House of Commons.

Too little attention has, I think, been devoted in the past to the wholesomeness of places where food is stored and prepared. Most practical sanitarians will agree with me that this neglect is likely to entail consequences more or less serious upon the food consumer, and in a still greater degree upon the food producers.

Turning to that portion of the subject with which I propose to deal more particularly, namely, the question of bakehouses, this attitude of general apathy is especially remarkable. In bread we have to deal with an article of prime necessity ; it is the staple and essential factor in all dietaries, and every citizen is directly concerned in matters affecting its cost, its purity, and its methods of production. Under such circumstances, then, it seems hardly credible that, on a moderate estimate, one half of the bread supplied to Londoners is sent out from cellar bakeries, or, in other words, that it is manufactured in underground places that violate the first principles of sanitation. This estimate, it may be at once acknowledged, is only approximate, as it is impossible to obtain anything like a comprehensive statement of facts and figures. In my own district of St. George-the-Martyr, Southwark, I find that out of 67 bakeries, 23 are situated altogether, and 9 partially, in basements ; an average which is exceeded in other metropolitan districts. In considering the source of the total output of bread, moreover, the fact must be taken into consideration that some of the above ground bakeries carry on business on a very extensive scale. On the whole, however, I think we may take it as a fairly correct assumption that about one half of the Londoner's daily bread is derived from underground bakeries.

According to the Census of 1891 there are no less than 18,029 bakers in London, and 84,158 in England and Wales. (b) These figures do not include the pastrycooks and confectioners, many of whom work underground, but whom I exclude, as they are not directly concerned in the production of bread. The bakers, however, constitute a large and important class, and when we take into consideration the wives and children dependent on their exertions, it will be evident that our present discussion directly affects the interests of a large section of the industrial community.

The lot of the journeyman baker is neither a healthy nor an enviable one. From the nature of his occupation he is placed in an environment that saps his strength and too often makes him prematurely aged. His face is thin and pale, his shoulders are rounded, and his whole look suggestive of chronic ill-health. Nor is this to be wondered at when we consider the fatiguing nature of his work, which is carried on through the night and far into the next day. He is exposed to damp and to great and sudden changes of temperature, and he habitually breathes an atmosphere which is charged with dust, with the fumes of coal, with the products of respiration, and not infrequently with actual sewage contamination. In consequence of the unhealthiness of the employment the young journeyman changes his occupation whenever he is able, and thus swells the mortality figure of some other trade. His place, however, is quickly filled up by recruits from the country, or by apprentices from Scotland and the West of England.

Dr. Ogle's tables of comparative mortality of males between 25 and 65 years of age, founded upon the death registers of 1880-1-2, offer some suggestive figures. From them we learn that in 100 different occupations bakers occupy the following relative positions : in suicide they come third, in alcoholism seventh, in liver disease eleventh, in diseases of the circulatory system eleventh, and twelfth in diseases of the nervous system. Many of these diseases may be traced to the abuse of alcohol, an evil habit which is doubtless fostered by the fatigue consequent upon the overwork, the long hours, the want of sleep, and the poisonous atmosphere to which the journeyman baker is exposed. It may be remarked that Dr. Ogle's tables do not confirm the high rate of mortality from consumption and diseases of the respiratory organs testified to by other authorities. This apparent anomaly is possibly explained by the fact that a small proportion only of the total number of bakers included in his tables are exposed to the bad environment met with in London. In short, his figures deal with the state of the trade generally, as apart from the Metropolis, and in this way they are diluted, so to speak, with the more favourable results obtained from provincial bakeries.

(a) Read at the Sessional Meeting of the Sanitary Institute, Feb. 14th, 1894.

(b) Since the Census of 1891 the bakers have added 13,126 to their number.

Among the diseases to which bakers are specially liable may be mentioned rheumatism, colds, erysipelas, and a form of eczema, due to the irritation of the flour, and known as "baker's itch." They are peculiarly liable to rupture and Malgaigne, indeed, states that their tendency to that affection is three times that of other trades. This observation is readily accounted for by the fact that the baker has to lift heavy sacks weighing 280 lbs. Another common affection of bakers is flat-foot, a deformity that produces a peculiar gait, and is also due to long standing and the habitual lifting of heavy weights.

As to the hours of work, from personal inquiries among the journeymen I find that seventy-two hours work weekly is a fair average in the better class trade, with Saturday evening and Sunday free. Nor is it easy to see how, with the present system of bread-making by hand, this time could be materially shortened. In the poorer neighbourhoods, where what is known as a "cutting" business is conducted, the baker works from eighty-four to a hundred hours weekly, and in addition frequently bakes dinners up till half-past one o'clock on Sunday.

Perhaps the best way to form an idea of the realities of a cellar bakehouse will be to draw a picture of such a place, sketching in the details from facts that have come under my own observation.

First of all we enter a baker's shop from the street and descending a trap door, climb down a steep ladder into the bakehouse. We then find ourselves in a cellar, some 20 or 30 feet in length, and 10 or 12 feet in breadth. It is in fact an ordinary basement cellar 6 or 7 feet high, and is lighted by gas-jets. Its roof is unceiled, and between the boards covering in the warped rafters are many cracks which open directly into the shop above. A portion of its floor-space is occupied by a slightly raised wooden platform on which are ranged a number of sacks of flour. Along one of its sides are placed the kneading troughs, large wooden boxes, which are fixed immovably against the damp and white-washed wall. The oven stands at one end of the bakehouse, away from the sacks of flour, and consists of a long deep chamber built of unglazed bricks. Its furnace is fed with coal, a supply of which lies in a loose heap close by. In the darkest corner of this underground bakery stands a kind of open cupboard, in which a water-closet is placed.

In the cellar thus fitted up are carried on all the operations of mixing, kneading, and baking the dough, in addition to which it often serves for storing the loaves of bread.

On descending the stairs the visitor finds himself plunged into a hot and stifling atmosphere. Pursuing his investigations he will find that the air is vitiated from many sources, for instance, there is the active contamination of the flaring gas-jets, while the furnace fills the place with sulphurous fumes, more especially when the journeyman economises fuel by closing the damper. The air is further charged with moisture and with other products derived directly from the baking of the bread. Sewer-gas may enter through the drain openings in the floor, the more so as the grating traps are often worthless. It may enter, moreover, through a defective closet soil pipe. Further pollution is caused by the ground air and damp which are sucked up into the heated cellar through the faulty flooring. But this is not all, for in low-lying districts there is the danger that in times of heavy rain-fall the sewage may force its way through the drain-pipes into the bakehouse. It is easy to see that the introduction of a flood of sewage in this way may bring the germs of typhoid and other filth diseases into direct contact with the loaves of baked bread.

Ventilation, in any real sense of the term, is absent, and indeed, under the circumstances we have pictured, is impossible. An inlet grating usually exists at the level of the street, but as a rule it is kept carefully closed by the journeyman, who is morbidly susceptible to draughts. In most cases, again, there is another small inlet at the back of the cellar, but this second ventilator is almost invariably covered up by means of a sack. It will be seen, therefore, that not only is the air systematically poisoned from within, but also that no provision is made for that constant renewal from without which is essential to health. We may safely assert that no man could habitually work in an atmosphere even approaching that which has been portrayed without sooner or later sustaining serious injury to his health.

Our description, however, has by no means exhausted the evils incident to a bad underground bakehouse. In many of these places the unhappy journeyman is actually shut up for 12 hours or more at a stretch, and during that period adds his quota to the general impurity. At times he smokes, or uses tobacco in the still more objectionable form of chewing. Now and then dogs and cats are found in the cellars. Other forms of animal life include rats, mice, black beetles, cock-roaches, ants, and spiders, the smaller insects often being present in almost incredible numbers. Then the moist and heated atmosphere is favourable to the rapid decay of vegetable matter, and this takes place in the scraps of dough and refuse flour which collect in the hollow sides of and beneath the kneading troughs. The same conditions act on the coal, and cause it to give off various injurious gases.

Bread, as everyone knows, is peculiarly liable to absorb moisture and gaseous substances. When stored in a badly arranged bakehouse, therefore, it can hardly escape deterioration. Moreover, when prepared under such conditions, it is liable to be injured at every step of its manufacture. The flour becomes damp, musty, and sour, the sponge and dough contaminated by the sweating arms of the journeyman, while on all sides it is exposed to the risk of sewage and of other noxious emanations. Lastly, the water with which the flour is mixed is often obtained from the same cistern which supplies the water closet, a system which is nothing less than an open invitation for the entrance of sewage matter into an important and universally used article of food.

In London, there are between 30 and 40 "model bakeries," that is to say, places where baking is carried on in a cleanly and scientific way amid wholesome surroundings. This number does not include the wholesale factories, of which there are several of large size. It will be sufficient here if I briefly lay down the principles which should guide the construction and management of a sanitary bakery.

First, the building itself should be specially built for the purpose, with strong walls and a plentiful supply of windows. Separate and lofty rooms should be provided for storing flour, for mixing and kneading the dough, for baking, and for storing the bread. The flour-loft should be placed at the top of the building, and all the sacks should be conveyed thither by means of a lift, so as to spare the workmen as much as possible from the laborious and dangerous work of hauling about heavy weights. The mixing and kneading room should be provided with movable iron troughs. The kneading, as well as the mixing to be conducted by means of machinery wherever possible, in order to avoid the handling of dough or flour by the workmen. Then a special provision should be made for thoroughly cleansing the empty sacks before they are returned to the miller.

These various rooms should be light, airy, and lofty, and be kept with the most scrupulous regard to cleanliness. Much will depend on the construction of the room. The walls, ceiling, and floor of each room should be of smooth and non-absorbent material, such as glazed tiles for the walls and roofs, and hard wood or tesselated pavement for the floor. The windows should reach to the ceiling and be kept permanently open at the top. Additional ventilation could be provided by means of Tobin's tubes and appliances, but in all cases it is imperative that all such apparatus should act automatically and be beyond the control of the workmen. As much daylight as possible should be admitted to every part of the building, and no part of the bakehouse must be below the ground-level. Where artificial light is wanted, it would be best obtained from electric lamps. The water used for mixing the dough must be provided from a special and separate cistern, or better still, direct from the rising main. All sanitary conveniences, including wash basins and baths, should be placed in a basement, or in some place quite apart from the main building.

The ovens themselves may be heated in various ways. Some of the most cleanly and convenient of the latter means are by gas or by tubes containing superheated steam. If coal or coke be used, it is important to insist that the furnace room must be freely ventilated and that on no account is the flue to be closed by a damper.

Let us next glance briefly at the state of legislation with regard to bakehouses.

Before 1863 no special legislation existed. In that year, however, the Bakehouse Regulation Act was passed. The measure in question was introduced at a time when public attention had been pointedly drawn to the unhealthy conditions under which baking was carried on. The duty of enforcing this first Act of 1863 was imposed on the local authorities. As a result of the report of a Royal Commission on Factories and Workshops in 1876, the Factory and Workshop Act of 1878 was passed, and at the same time the Bakehouse Act was repealed. For some unaccountable reason, and against the advice of the Commission, the regulation of bakehouses was transferred from the local authorities to the already overburdened factory inspectors, who numbered six only for the whole of London. In 1883, on the passing of the Factory and Workshop Amendment Act, followed a re-transfer of the duties from the factory inspectors to the local authorities.

The present law regarding retail bakehouses, so far as London is concerned, is incorporated in sections 26 and 27 of the Public Health (London) Act, 1891. The provisions of the Act of 1878 are contained in sections 34, 35, and 81. These sections, repeated in clause 26 of the Public Health (London) Act, apply to such bakehouses only as are situated in any place that contains, according to the last published census, a population of more than 5,000 persons. Section 34 runs as follows:—"Where a bakehouse is situate in any city, town, or place containing, according to the last published census for the time being, a population of more than 5,000 persons, all the inside walls of the rooms of such bakehouse and all the ceilings or tops of such rooms (whether such walls, ceilings, or tops be plastered or not) and all the passages and staircases of such bakehouse, shall either be painted with oil or varnish, or be lime-washed, or be partly painted or varnished and partly lime-washed; where painted with oil, or varnished, there shall be three coats of paint, or varnish, and the paint or varnish shall be renewed once at least in every seven years and shall be washed with hot water and soap once at least in every six months; where lime-washed the lime-washing shall be renewed once at least in every six months. A bakehouse in which there is any contravention of this section shall be deemed not to be kept in conformity with this Act."

Section 35 of the 1878 Act states that a place on the same level with the bakehouse and forming part of the same building shall not be used as a sleeping place unless it is constructed as follows; that is to say:—"It must be effectually separated from the bakehouse by a partition extending from the floor to the ceiling, and unless there be an external glazed window of at least nine superficial feet in area, of which at least four-and-a-half superficial feet are made to open for ventilation." There is no apparent reason why the operation of this section should have been confined to urban districts. Surely, in the interests of the sleeper or of the bread consumer—whether rustic or cockney—it is desirable that the section should be of general application. Section 81 of the 1878 Act provides that if section 34 be contravened, the occupier of the bakehouse shall be liable to a fine not exceeding £10.

The sections of the Act of 1883 applicable to bakehouses, and repeated in clause 26 of the Public Health (London) Act, are clauses 15 and 16. Section 15 relates exclusively to places which were not let or occupied as bakehouses before the 1st of June, 1883. The clause provides that it shall not be lawful to let or suffer to be occupied as a bakehouse, or to occupy as a bakehouse any such place unless the following regulations are complied with:—(1) No water closet, earth closet, privy, or ash pit shall be within, or communicate directly with the bakehouse. (2) Any cistern for supplying water to the bakehouse shall be separate and distinct from any cistern for supplying water to a water-closet. (3) No drain or pipe for carrying off fæcal or sewage matter shall have an opening within the bakehouse.

It is to be regretted that this section is not applicable to bakehouses let or occupied as such before as well as after the 1st June, 1883.

Section 16 relates to all bakehouses, whatever may be the date of their construction or first occupation. It provides that where a court of summary jurisdiction is satisfied on the prosecution of a local authority that any place used as a retail bakehouse is in such a state as to be, on sanitary grounds, unfit for use or occupation as a bakehouse, the occupier of the bakehouse shall be liable, on summary conviction, to a fine not exceeding forty shillings, and on a second or any subsequent conviction, not exceeding five pounds. The court, in addition to, or instead of, inflicting such fine have it in their power to order means to be adopted by the occupier, within a time named in the order, for the purpose of removing the ground of complaint, and may, on application, enlarge the time so named, but if after the time so originally named or enlarged by subsequent order, the order is not complied with, the occupier will be liable to a fine not exceeding one pound for every day that such non-compliance continues.

The Vestry of St. George-the-Martyr, Southwark, is, so far as I know, the first local authority to have instituted proceedings under this 16th section since the passing of the Act in 1883. The case resulted in a fine of 40s.

Section 17 of the 1883 Act, subsection 2, has been repealed by section 27 of the Public Health (London) Act, 1891. The latter clause reads as follows:—"If any child, young person, or woman, is employed in a workshop, and the medical officer of the sanitary authority becomes aware thereof, he shall forthwith give written notice thereof to the factory inspector for the district."

The only remaining special legislation affecting retail bakehouses is to be found under section 26, sub-sections 1 and 2, of the Factory and Workshop Act, 1891. This clause obliges every person within one month after opening a bakehouse to serve a written notice upon the district factory inspector, acquainting him with the fact. The clause further imposes upon the inspector the duty of forwarding the notice forthwith to the sanitary authority of the district in which the bakehouse is situate.

The chief conclusions at which I have arrived may be stated somewhat as follows:—

1. That it is advisable by means of a Select Committee of the House of Commons to inquire into the bakehouse question.

2. That in case the Committee advise fresh legislation they shall prepare a bill incorporating their recommendations with the Public Health (London) Act, 1891.

3. That it should be rendered an offence to occupy as a bakehouse any cellar or place completely below the level of the street, unless it had been so occupied before a certain fixed date.

4. That all bakehouses be compulsorily licensed, and that such license be renewable annually.

5. That the granting of licenses be vested in the London County Council.

6. That uniform metropolitan by-laws regulating the conduct of the retail bakeries be made by the County Council and confirmed by the Local Government Board.

7. That such by-laws shall cover (a) the regulation of the conduct of the business; (b) the regulation of the structure of the premises; (c) the regulation of the mode in which application is to be made for sanction to establish anew the business of a baker in the County of London.

8. That the by-laws relating to structure, and comprised under heading "b" do not apply to existing bakeries until after the lapse of a certain number of years.

9. That the question of compensation for disturbance of existing rights in bakeries be taken into consideration by the Parliamentary Committee.

10. That no dealing with the question of the regulation of bakehouses will be complete unless it investigates the relations between the millers and bakers. At present the small tradesmen are often completely under the thumb of the capitalist millers.

11. That inspection of bakehouses should be more systematic and thorough. To fulfil this condition an increase of the staff of sanitary inspectors is imperative.

12. That a more intelligent knowledge of the whole question of their bread supply is desirable on the part of the public.

13. That the sacks of flour should be reduced from 280 to 140 lbs.

To my mind, the ill-health of the baker is in the main the result of the bad surroundings in which he works. If baking be carried on in well-ventilated places, with a perfect sanitary environment, there is no reason why it should be a particularly dangerous or unhealthy trade. It is open to question how far the State should be called upon to fix the hours of labour of the journeyman baker Without entering, however, into the discussion of that difficult and complex economical problem, it may, I think, on the other hand, be emphatically asserted that there is much in the present condition of the retail bakehouses which calls for stringent legislative interference.

◆

Selected Prescriptions and Therapeutic Notes.

68.—Lozenges to be used in Congestion of the Pharynx and Larynx :—

℞ Chloride of ammonium, in powder, 700 gr. ;
Tragacanth, in powder, 140
Refined sugar, „ 280
Black currant paste, as much as is sufficient.

Mix the ingredients, and add the paste until the whole mass weighs 1 lb. Divide into 350 lozenges of 20 grains each, and dry in a hot-air chamber at a moderate heat. Each lozenge will contain about two grains of chloride of ammonium.—*Throat Hospital "Pharmacopœia."*

69.—Tannin as an Intestinal Antiseptic :— Tannin is one of the most efficient of all germicides for use as an intestinal antiseptic. We have for several years employed this agent as an antiseptic in intestinal catarrh, and with most excellent effects. When administered by the mouth we have usually given 3–5 grains in capsule two or three times a day ; but most useful results are also to be gained, especially in cases of pseudo-membranous catarrh of the intestines, by first washing out the bowels with a large quantity of hot water, and then injecting a solution of tannin of the strength of one drachm to a pint.—Dr. Baczkiewicz.

70.—Snuff for Acute Coryza :—

℞ Cocainæ hydrochloratis, gr. iss ;
Mentholis, gr. ijss ;
Acid. salicylatis, gr. viij ;
Acid. boracis, ʒj ;
Pulv. amyli, ʒiss.

Mix and reduce to a fine powder. Every two hours a pinch of the snuff may be taken, after blowing the nose.

71.—Ichthyol in Pruritus :—In the vaginal pruritus of pregnancy, ichthyol has been found very useful. It may be employed in the form of an ointment, made up with lanolin. In some of these cases it has given relief where carbolic acid and cocaine have failed. In the pruritus, also of diabetes, the drug has proved to be very useful, combined with fifty per cent. of glycerine.

72.—Gonorrhœa :—Ichthyol is now *de rigueur* in the treatment of this affection in Paris. The following is the formula :—

Ichthyol, ʒj ;
Water, ℥viij.

Three injections daily.

—*From our French Correspondent.*

◆

We understand that Mr. O'Callaghan, F.R.C.S.I., Surgeon to the Carlow County Infirmary, has resigned this surgeoncy, and is about to leave Ireland, and to take up his residence in Harley Street, London, where he will practise, chiefly the gynæcological speciality. Mr. O'Callaghan has recently benefited by the will of a patient to the extent of about £12,000.

Clinical Records.

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

Case of Progressive Muscular Atrophy, with commencing Bulbar Paralysis.

Under the care of Dr. Jas. Cagney,
Physician to the Hospital.

Patient, a man, æt. 58. The earliest symptoms had set in nearly two years ago. Treatment at the National Hospital was attended with a stay in the progress of the disease, and the patient was able to return for many months to his occupation, that of a sawyer. After a time the muscular atrophy extended slowly at first, and following more or less closely the typical distribution of the paralysis until in the recent cold weather it made very rapid advances, and the man was admitted as an in-patient at the Regent's Park Hospital at the beginning of the present month. The greater part of the upper extremities was then wasted. There was weakness but no wasting of the lower limbs, and the knee jerks were normal. Ten days later the speech became thick and there was special difficulty in pronouncing linguals. The tongue was tremulous and the lips at times slightly so. A week later the right knee jerk had almost disappeared. There was numbness and pains in the peroneal region, and diminished galvanic excitability of the peronei on both sides. Quivering of the tendons about the ankle-joints was caused by cold, and gave much annoyance when the patient sat in a draught. Deafness of sudden onset was partially cured by the removal of wax. The palate was asymmetrical but moved fairly freely ; the palatal reflex was abolished ; the tongue presented no change, and was protruded straight. Later it was protruded to the right and showed some inequality between its two sides but neither wasting nor fibrillary twitching. Laryngoscopic examination was negative. The pupils were unequal, the right being much smaller than the left, and reacting sluggishly to light and accommodation. Tremors of the lips had been observed but were not constant. The diagnosis of progressive bulbar palsy was based upon the changes in the tongue and soft palate and the change in speech. It was remarkable also that the case showed none of the spastic phenomena which characterise amyotrophic lateral sclerosis, the condition upon which bulbar palsy is said most often to supervene. On the other hand, the weakness without wasting of the lower extremities would be taken to imply degeneration of the pyramidal tracts. The deafness was probably not attributable to bulbar palsy. Points of incidental interest were the arrest of the disease for a long time and its rapid course afterwards under the influence of cold ; and its extension simultaneously to the medulla and the lower part of the cord. Dr. Cagney pointed out that amidst the general atrophy of the right arm and shoulder the upper part of the trapezius—Duchenne's *ultimum noriens*—remained. The shoulder in question was much lower than the other, a fact ascribed by the patient to his habit of carrying heavy beams of wood on it. The exemption of the upper part of the trapezius under these circumstances deserves prominence in view of the belief held by Eichhorst and others that use determines the incidence of atrophy in these cases. The patient had been the subject of incontinence and cystitis for two years before the disease showed symptoms.

Case of Hysterical Attacks simulating Partial Epilepsy.

The subject was a woman, æt. 32, married ; two children. She came to the Hospital for Epilepsy and Paralysis on October 11th, 1893. Three months previously she had had a cataleptic fit preceded by psychical and visceral auræ and attended with hemiplegia. The attack lasted five hours. When seen she presented anæsthesia and analgesia of the right side of the lip inside and out, and at the tip of the tongue, and loss of sensation of all kinds at the ends of the thumb and three fingers of the right hand. She thought these symptoms followed the fit, but Dr. Cagney regarded them as permanent stigmata. There was, besides, clavus, buccal, and conjunctival anæsthesia and irregular anæsthesia of the right side of the face. There was a second attack on November 28th ; similar auræ followed by paraplegia lasting two hours, and incessant yawning and facial contortions for twenty-four hours longer. When seen on December 6th the permanent stigmata were as before. There were signs of effusion into both temporo-maxillary joints; paresis and exquisite tenderness of the temporal muscle on the right and tenderness of the masseter and trapezius on the right; of the sterno-mastoid on the left, pain in legs and back; vertigo; a loud thudding tinnitus, and severe pain at the temples.

Dr. Cagney inferred that the attack was one of hysteria major ceasing with the epileptiform stage, and that the facial group of muscles had been alone or chiefly involved. He quoted M. Ballet (*Brain*, p. lv, 1891) who has written an instructive monograph on the subject. He said it was very necessary to recognise the nature of such attacks both to guard against error and also because the rarity of the grand attack of hysteria in England makes it desirable to take every opportunity of studying the minor manifestations of the disease.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, Feb. 23rd, 1894.

The President, Mr. J. W. Hulke, F.R.C.S., in the Chair.

CLINICAL EVENING.

Dr. Wilberforce Smith showed a case of phthisis in which a cure had followed the inhalation of carbolic acid. The patient was a man, æt. 25, who first came with signs of dulness, and moist sounds at the apex of one lung. The temperature was high and he was also suffering from *fistula in ano*. He went to the seaside where he lived under good hygienic conditions, and he used a large inhaler made from an ordinary hat box in which was suspended flannel charged with carbolic acid. He continued these inhalations for eighteen months and his present condition was apparently one of complete recovery.

Dr. Fletcher Little showed a lad, æt. 19, with an imperfectly developed sternum. The joint between the manubrium and gladiolus permitted free movement as did that between the gladiolus and the ensiform cartilage. The gladiolus itself was retracted during inspiration.

Dr. Sansom showed a case of aphasia in a girl, æt. 22. The case had commenced as one of right hemiplegia with very complete aphasia. The hemiplegia had since passed away, and she now could perform fine movements with the hands but the aphasia remained. Mitral stenosis was present and the origin of the hemiplegia was, he suggested, probably embolic.

Mr. Stanley Boyd exhibited a man, æt. 24, who had ruptured the anterior crucial ligament of one knee-joint, when playing football three years ago. There was effusion for 8 or 10 weeks, but he afterwards recovered sufficiently to walk and even run. Since then the joint had repeatedly given way, and he had recently wrenched it. After this the joint had more than once become locked in the semi-flexed position, and was reduced by manipulation or by flexion.

Mr. Croft remarked on the looseness of the joint and the power of antero-posterior movement in it which he considered to indicate that the anterior extremity of the external semilunar fibro-cartilage and the lower end of the anterior crucial ligaments, were both detached, the external semilunar cartilage being folded back into the intercondylar notch. He considered it would be justifiable to open the joint and ascertain the precise condition which could then be dealt with surgically.

Mr. W. C. Spencer recommended the application of the actual cautery to the lateral ligaments so as to shorten them.

Mr. Barker inquired if there was any grating indicating that the ligament had become detached along with a fragment of bone? In the latter case it would be easier to repair it.

Dr. R. W. Parker observed that where the crucial ligaments were destroyed there was displacement backwards of the tibia.

The President remarked that the function of the crucial ligaments was a vexed question. The anterior crucial ligament was supposed to become tense in extension, but this patient was unable to hyper-extend his joint.

Mr. Boyd, in reply, said that the tibia could only drop back if both the crucial ligaments were ruptured.

Mr. Battle showed a child, æt. 2½, who had suffered a compound fracture of the pelvis into the vagina. He had wired the broken bones together in front and passed a drainage tube through from the upper wound into the vagina. The child made a perfect recovery.

Mr. Battle also showed a girl, æt. 19, who had sustained a dislocation of the right hip on the dorsum ilii. There had been a history of lameness for eight years before this. It was repeatedly reduced but the dislocation recurred and so he made an incision over the joint which he found distended with blood-stained fluid. He easily reduced the dislocation and passed three ivory pegs through the head of the bone through into the acetabulum. The wound healed readily, the head of the bone remained in its place and there was now fairly free movement in the joint.

Mr. Battle finally showed a boy and a woman who had recovered after trephining for extraordinary hæmorrhage and whose cases would be described at the next meeting.

Dr. Arthur Davies showed a myxœdemic patient whom he had first exhibited in February 1892. Treatment by administration of thyroid gland in various forms had been continued since, but whenever it had been discontinued a relapse had occurred, the first indication of which was a sensible gain in weight.

Mr. Bland Sutton brought forward a young woman the sternal half of whose clavicle he had excised in June 1890 for myeloid sarcoma. There was at present no indication of the return of the growth and the patient was in good health. A bond of fibrous tissue had formed between the stump of the clavicle and the acromion, and the patient could perform all movements of the upper extremity perfectly.

Dr. Arthur Davies showed a youth, æt. 19, in whom he had diagnosed congenital dislocation of the sternal ends of the clavicles.

Dr. James Calvert showed a woman, æt. 27, whose respiration was entirely diaphragmatic when awake, being however, natural during sleep.

Mr. Storer Bennett exhibited a man, æt. 25, with a dentigerous cyst in the right upper maxilla. There was a swelling above the right upper central incisor on incising which pus and serum escaped. In the cavity a hard substance was felt which was found to be a tooth in the cyst with the crown inverted.

Dr. F. W. Mott read a paper on a case of

MULTIPLE NEURITIS.

W. H., æt. 34, fruit salesman, admitted under Dr. Green into Charing Cross Hospital, April 26th, for kidney disease. Patient had not had syphilis, gonorrhœa, or rheumatism. For some weeks past had suffered with chills and sweats and epistaxis. Five days before admission he had swelling of the right knee and pain in the leg, and hand of the same side. When examined it was found that he had pain, swelling, and redness in right arm and leg with patches of œdema and swelling of joints. The arm was stiff; there was albumen and blood in the urine, and there was considerable pyrexia varying between 102° and 103°·6. No cardiac or pulmonary disease detected. About a week after admission diarrhœa with hæmorrhage from bowel occurred, and it was thought that the case was possibly typhoid and not rheumatism. The diarrhœa ceasing after a week. The temperature again began to rise to 103° and more, and there was more evidence of paralysis in right limbs and some anæsthesia. I was asked to see the case, and found reaction of degeneration in the muscles of the right arm and leg, and a few days later coincident with a pyrexial exacerbation commencing reaction of degeneration was found in the left limbs. Moreover, there was marked anæsthesia and analgesia in the paralysed parts. The bladder and rectum not being affected, I diagnosed multiple infective neuritis. The pyrexia lasted two months, and there was a decided relationship between the paralysis of groups of muscles and the pyrexial exacerbations. On many occasions I examined the blood during the pyrexia, and I found a great excess of leucocytes and micrococci. Cultivations were made under strictly antiseptic precautions of a diplococcus, but Dr. Arkle and myself were unable to produce any poisonous effects by the introduction of the chemical products or the organisms themselves into rabbits. The man is alive and in good health to-day, but completely paralysed in his lower extremities. There has been some improvement since he was shown at the Society in November last. He has regained power of flexion and extension in the hip, ankle, and knee-joints, but is still too weak to stand. I am unable to assign the cause of the obvious septic infection, unless it be by a pyelitis, for he always had pus corpuscles and micro-organisms in an acid urine when I examined it. In conclusion, I have to add that I am indebted to Dr. Green for kindly placing the man under my care.

DIPHTHERITIC PARALYSIS SUDDENLY FATAL OWING TO TEA GETTING INTO THE BRONCHIAL TUBES.

Dr. **Hale White** read the account of a man who three weeks after a severe attack of diphtheria was attacked with paralysis. *On admission.*—The arms and legs are very weak and there is impaired movement of the abdominal muscles. Food regurgitates through the nose and there is unilateral paralysis of the palate. Muscular and tactile sensation is slightly impaired. When drinking some tea he suddenly began to cough, this ceased in a few seconds and the patient became very distressed in his breathing, sitting up in bed in great distress and panting for his breath exactly as if he had been suffering from asthma. There was at no time any evidence that the larynx was obstructed. The difficulty of breathing got worse, towards the end the patient became very livid and he was dead in less than ten minutes from his taking the tea. The pulse continued good till the end. At the autopsy an ounce and a half of tea was found in the bronchial tubes and this was absolutely the only cause for death. At the bedside it was recognised that probably a little air had got into the air passages but it was hoped that either the patient would be able to cough it up or that it would cease to irritate and that the paroxysm would pass off. Dr. Hale White pointed out that although there were very rare instances on record in which the impaction of solid food in cases of diphtheritic paralysis had caused death, he had not come across any case in which such a small amount had caused death by spasm of the bronchial tubes which was in all probability what happened in his patient, the result being no doubt favoured by the weakness of the abdominal and deglutatory muscles.

Dr. **Sansom** suggested that Dr. Mott's case was possibly one of influenza. He referred to a case which showed distinctly the cardiac sequelæ of influenza, although he was supposed to be the only one in the household who escaped. In another case, that of a girl, æt. 13, under his care in the London Hospital, neuritis of both legs developed after influenza, there being "dropped feet" and no response whatever to electricity. That case occurred at the beginning of the influenzal epoch, and it commenced with pain in the calves and tenderness on pinching. He mentioned another case, that of a boy who, while influenza was rife, found himself unable to get upstairs without clinging to the banisters. On examination there was distinct pyrexia and evidence of neuritis in the right leg. Later there was rapid wasting of the lower thoracic muscles and of the upper part of the right rectus abdominis, so that a local antero-polio-myelitis must have been associated with the neuritis. Many such cases had been recorded abroad, and he thought the strong analogy to beri-beri pointed also equally strongly to its being the influenzal form of neuritis.

Mr. R. W. **Parker** said that he considered it difficult to understand that diphtheritic paralysis could be a form of peripheral neuritis. In all the cases he had examined he had failed to detect any pathological changes in the nerves.

Dr. **Goodall** remarked that in most of the cases he had seen it was difficult to refer the lesion to a central origin. They were typical instances of peripheral neuritis, and Dr. Sidney Martin's work seemed to have put this matter beyond doubt. He considered Dr. Hale White's case very uncommon. He had seen symptoms of abductor paralysis develop very suddenly, causing necessity for immediate tracheotomy. In all cases where swallowing could not be properly performed recourse should be had to feeding with a nasal tube.

Dr. **Kanthack** said he had examined the cultures from Dr. Mott's case, and found that there was a diplococcus not met with in the skin. He recommended the consecutive injection of the cultures day by day into animals in order to keep up a condition of chronic infection. Martin's experiments undoubtedly proved that the neuritis was due to the toxin of diphtheria. It was not really a neuritis but a primary nerve degeneration.

Dr. **Hale White** mentioned that he had published a case in the last volume of the Clinical Society's "Transactions" which resembled the one related by Dr. Mott. The patient suffered from septicæmia, and then developed all the symptoms of peripheral neuritis. After amputation the stump healed, and the paralysis passed off.

Dr. **Percy Kidd** asked Dr. Mott if he had examined the medulla oblongata?

Mr. **Gould** mentioned a case in which solid food passed into the air passages in diphtheritic paralysis. The patient, a child, was eating bread and butter when he suddenly choked, and on tracheotomy being performed the masticated bread and butter ran out of the tracheal wound. The boy ultimately did well.

Dr. **Glover** thought that Dr. Mott dismissed too lightly the element of alcohol in his case, for the man had confessed to taking a quart of beer daily.

Dr. **Mott**, in reply, said that there was no history of influenza, and, moreover, the case very closely resembled others which had been reported before influenza had become common. He had studied carefully the notes of a case of post-influenzal neuritis, but the clinical picture was not the same. He thought that very possibly there must have been some septic source, but if so it had not been discoverable. The amount of alcohol taken was not sufficient to produce the disease.

Dr. **Hale White**, in reply, thought that his patient had possibly some deficiency of power in the larynx, but that had not produced the fatal result. No microscopical examination of the medulla was made because the symptoms seemed to be completely explained without it. He held it to be absolutely proved that the diphtheritic paralysis was a degenerative neuritis.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, February 2nd.

Dr. **Macan** in the Chair.

EXHIBITS.

Polypus of Uterus.—Dr. **Lane** exhibited the case of L. K., unmarried, who stated her age to be forty years, who came to the City of Dublin Hospital on Nov. 29th, 1893. She had been attended by a gynæcologist for a year previously owing to her suffering from a profuse red discharge, accompanied by slight pains in hypochondriac and right and left iliac regions, and sometimes vomiting. This condition of affairs continued till Feb., 1890, when the discharge lasted fourteen days, and was rather heavy; and from that date the changes, as a rule, returned every five weeks and lasted from fourteen days to three weeks. In Oct., 1893, the discharge only lasted nine days, but it was very heavy and was accompanied by intense pain and vomiting. The patient felt very weakly after this. On examination in hospital, Nov., 1893, a tumour was found projecting into the vagina, but owing to the small size of the vagina and the tenderness of the lower part of the abdomen I was unable to say definitely whether it was a polypus or an inverted uterus. I was afraid to use a sound, both on account of the hæmorrhage and not knowing what the condition of the parts were, so I asked the patient to come into hospital, which she did in a few days after. When I next examined there was not so much tenderness, so I was enabled to find the uterus lying above the tumour and directed to the right side. I was also able to reach the cervix, which was greatly dilated, cupping the tumour. I then passed a sound and determined to try and remove the tumour at once. The patient was anæsthetised, and then I was able to make out all that was necessary for me to know. I caught the tumour near the pedicle with a vulsellum and assisting with my two fingers in vagina, I was able to twist off the tumour. I had not a curette with me, so I simply washed out the uterus, there being but a very slight discharge. I have seen the patient twice since she left hospital, and although the cervix has contracted very much yet it has not got back to what it should be. There had not been a change up to the time I last saw her.

Dr. Atthill said the specimen illustrated the rule that when a uterine tumour becomes vaginal the hæmorrhage, as a rule, ceases, or becomes very moderate in amount.

Double Ovarian Tumour.—Dr. W. J. Smyly exhibited a specimen of double ovarian tumour. He said the specimen was removed from an old lady of about sixty years. Her abdomen was enlarged to about the size of an eight months' pregnancy. On examination he found, on the right side, a tumour which was slightly movable, and in front there was free ascitic fluid. On making a vaginal examination he found a cystic enlargement in Douglas' pouch. The uterus could not be palpated. He diagnosed a double ovarian tumour, one above the uterus and the other in Douglas' pouch. On opening the abdomen fluid escaped and he then removed an ordinary cyst. He ligatured the pedicle with catgut and found another cyst about as big as the fœtal head in the posterior cul-de-sac. This was a proliferating one. It also contained a small amount of sebaceous matter, while the solid portion of it appeared to have a fibrous look. In fact, the patient presented a whole museum of pathological specimens of the ovary.

Tumour of the Broad Ligament.—Dr. Macan exhibited a specimen of tumour of the broad ligament. On removal it was adherent to three pieces of the omentum, but in endeavouring to separate the adhesions it burst and blood and coagulum escaped. There was difficulty in stopping the hæmorrhage, and it looked very like an extra-uterine gestation. When he removed it he could pass a probe along the tube, but Dr. Earl, to whom he submitted the specimen, was entirely against the theory of gestation. He (Dr. Macan) could only say that it was a blood cyst of the broad ligament.

VAGINAL HYSTERECTOMY.

Dr. Lombe Atthill read a paper on Vaginal Hysterectomy, specially with reference to its performance in cases of malignant disease of the uterus. After expressing his disbelief as to anything more than temporary benefit following supra-vaginal amputation of the cervix in such, he related three cases in which the disease originated in the interior of that organ, and in which the operation was performed with marked success. In one of these, four years had since elapsed, and the patient continues to enjoy perfect health. The other two were comparatively recent cases—in one about a year and in the other only nine months having elapsed since the date of the operation; they were, to all appearances, however, cures. Dr. Atthill considered these typical of the class of patients on whom hysterectomy should be performed, and that, too, at the earliest possible date. He hesitated to recommend its performance if the disease has extended downwards from the cavity to the cervix, or in cases in which the uterus, even to a limited extent, is engaged. He also considered that where the cervix is the primary seat of the disease, the operation of hysterectomy, though, perhaps, justifiable, is seldom successful in preventing its recurrence, and agreed with Dr. Williams that in such cases the cancer cells have a tendency to invade the adjacent tissues rather than to spread upwards towards the body of the uterus.

Dr. W. J. Smyly said he met the lady recently on whom Dr. Atthill performed the first operation, and she was in perfect health and spirits. He thought that one case like that would be quite sufficient to prove the value of the operation. He thought the reason why this operation had made such little progress in these countries was, that they seldom got cases to operate on in a sufficiently early stage. He thought that whenever a woman had a considerable hæmorrhagic discharge, it was the duty of the medical attendant to examine her, or send her to some one who would do so.

Dr. Horne said—At the age of fifty the uterus had virtually ceased to be an active organ, and therefore its removal did not carry the same amount of responsibility as it would before that age; but as the patient was only forty years of age, the question arose whether he was justified in performing hysterectomy unless after a microscopic examination,

Dr. Bates referred to Dr. Martin's (of Berlin) method of operating. He saw him perform the operation, and he commenced from below; and when about two-thirds of the uterus was separated from its attachments, he commenced to separate the uterus from its attachment to the bladder, and then anteverted it, and separated the small portion that remained. He also performed it for cases of procidentia.

Dr. Macan did not consider that a thickening of the broad ligaments was an absolute contra-indication, because they might have an inflammatory thickening of the broad ligaments. In cases of cancer of the cervix he also thought it much better to operate, because they would, at all events, stop the hæmorrhage and the fœtid discharge. He said Leopold looked upon two years as the limit beyond which they might look upon the patient as cured. He himself had a sad illustration in a patient who died three years after, and for that reason he could not look upon two of the patients to-night as cured until they heard a little more about them. He said Leopold removed the uterus for fibrous tumour, and if the uterus was of very considerable size it was better to err on the side of operating.

Dr. Atthill, in reply, thanked the members for their interesting observations. He had no intention of bringing anything novel or wonderful before them, but simply a few interesting cases. The operation of hysterectomy was a simple one, and no one would hesitate to remove the cancerous uterus just as they would remove a breast. He thought as long as the operation was safe they were perfectly justified in doing it, even if the cancer recurs. He entirely agreed with the President that it was best to err on the side of mercy, and relieve the patient's horrible condition by operating, even if the operation would be a useless one otherwise. Dr. Macan very properly criticised these cases as cases of cure, but what he (Dr. Atthill) meant to convey was that they tended to prove that there were cases of cure. He did not understand the advantages of the operation mentioned by Dr. Bates as done by Dr. Martin.

The Secton then adjourned.

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, Feb. 15th.

The President, Mr. George Eastes, in the Chair.

Clinical Evening.

Case of Tubercular Iritis.—Mr. A. Quarry Silcock showed a case in a boy, æt. 12. There was a mass of vascularised exudation about the size of half a pea, at the inner end of the horizontal diameter of the right cornea, covering the anterior surface of the iris and filling up the corresponding part of the angle of the antorior chamber. Numerous punctate deposits of exudation were seen on the posterior surface of the cornea and in its deepest layers. There was slight ciliary injection and posterior synechiæ were numerous. Vision: fingers only at eighteen inches, tension normal, fundus invisible. Duration of disease, two months. Left eye normal. There were signs of phthisis in right lung.

Case of Gummatous Synovitis of the Right Knee.—Mr. D'Arcy Power showed a boy, æt. 14, who a week before admission into the hospital had pain and swelling of the right knee, and felt weak and ill. On admission there were many ulcers on the trunk, head, and limbs, these healed rapidly under full doses of hyd. c. cret. At the present time there is chronic laryngitis. The glandulæ concatenatæ are "shotty." The right knee is uniformly enlarged and the joint distended with fluid. Thickened synovial membrane can be felt in the superior cul-de-sac. The case seems to be one of true gummatous synovitis rather than perisynovitis or of gummata in the cancellous tissue of the bone. The chronic laryngitis, deep scarring of the skin, and absence of any evidence of ulceration of the articular cartilages distinguish it from tubercular arthritis.

Case of Progressive Muscular Atrophy.—Dr. Cagney showed an interesting case with commencing bulbar paralysis in a man, æt. 58. He also showed a case of hysterical attacks simulating partial epilepsy in a woman, æt. 32. These cases will be found in another column under the head of "Clinical Records."

Dr. W. R. Dakin read a paper on

MODERN METHODS OF TREATING POST-PARTUM HÆMORRHAGE.

The author was of opinion that in view of two recently established methods of dealing with post-partum hæmorrhage and its immediate results it would be profitable to formulate a new line of procedure for use in cases when this accident occurs. The two methods of treatment alluded to were (1) plugging the body of the uterus, and (2) the infusion of saline (inert) fluids into the circulation. After mentioning the last resource available in intractable cases of uterine relaxation up to within a few years ago, namely, the injection of a solution of an iron salt into the uterus, and the means for supplying the blood-vessels with a circulating fluid by the transfusion of blood when hæmorrhage had occurred to a degree likely to be fatal to the patient; all the serious dangers attending the application of each remedy, the method of performing each of the operations here recommended in suitable cases was described fully. It was shown that they were both very simple, and required with one exception (a canula) no special instruments, and could therefore be undertaken before the patient had lost as much blood as to be in danger of life. The two methods were shown to be in accordance with physiological principles. Cases were described illustrating the valuable results obtained by this means, and reference made to the experiences of others. The advantages of plugging in some cases of laceration of the body or cervix uteri was shown, and other methods of treating the acute anæmia were discussed. A summary of treatment was then suggested for severe cases of post-partum hæmorrhage, as follows: if the placenta is still unexpelled it must be removed. Expression failing, the hand (aseptic) is to be introduced as far as necessary and the placenta removed from the uterus, by peeling it off the placental rib if necessary. If hæmorrhage occurs after the placenta has been expelled order hot water to be in readiness. Several quarts will be required. The temperature should be about 118° in the douche-tin or vessel containing the water. When no thermometer can be obtained the water should be almost as hot as the hand can bear. Place the patient on her back and pass a catheter if there is time. Then, in the order given, joining on to the next as each one fails after a few seconds trial, (1) compress and knead the uterus through the abdominal walls with both hands, one hand tying along each side of the uterus with the fingers pointing to the pubes; (2) keeping up the pressure against the vertebral column with the left hand laid across the front of the uterus, pass the right hand up to the fundus, clear out clots, and compress the uterine wall between the two hands; (3) pass the internal hand into the posterior vaginal cul-de-sac, and press the fundus down on to it with the external one, so that the uterus is squeezed in an antiflexed attitude. It can be thus held with little or no bleeding until the hot water is ready; (4) inject the hot water into the uterus, passing the nozzle right up to the fundus, and ensuring a free escape for the excess. If the uterus does not contract after two or three quarts have been used, or relaxes again after contracting, (5) plug at once as described. If a patient is suffering from severe acute anæmia and collapse do transfusion. If she is moderately blanched do auto-transfusion, or slowly inject saline fluid into the bowel.

Dr. **Herman** doubted whether plugging the uterus did actually cause contraction, and remarked that it was not invariably effectual in staying the hæmorrhage. From the reports of the series of cases in which this method had been adopted it was obvious that the majority were not cases of severe post-partum hæmorrhage. He laid stress upon the fact that the main element in the treatment of post-partum hæmorrhage was prevention rather than cure.

Dr. **Milson** remarked that Dr. Dakin had not referred to the value of galvanism in controlling post-partum hæmorrhage. In his experience he had found it of great use, and he had seen it apparently save life in two instances. A Gaiffé's battery could easily be carried in a midwifery bag, being not much larger than an ordinary dissecting case. It had the advantage of being very simple in construction, could be started into action in about a minute, and the generating agent being a powder of persulphate of mercury, there would be no risk of damage to the bag.

Dr. **Boxall** proposed bandages of felted cotton known under the name of lintine as a suitable material for packing the uterine cavity. If, after being rendered aseptic, the bandages be rolled and coated with a layer of gutta percha tissue they take up but little space and in a compact form could be always available. As regards hot-water injections, it was not so generally recognised as it should be that the temperature of the water should certainly not be less than 110° F. nor more than 117° F., for if merely lukewarm involuntary muscle is relaxed, and if too hot, is paralysed by its action, and the hæmorrhage in either case thereby increased rather than diminished. He was glad to find that Dr. Dakin, in summarising the measures which should be adopted in the treatment of post-partum hæmorrhage, had not omitted to mention relief of a distended bladder by catheter, for it was a point the importance of which is apt to be overlooked. Dr. Boxall would have included in the list of means at our disposal hypodermic injection of ergotinin as a valuable adjuvant to other measures.

Dr. **Leith Napier** said that neither theoretically nor practically was the use of gauze plugging comparable with efficient manual compression of the uterus; in a limited number of cases, namely, those in which there was atony at the placental site (so-called paralysis), the introduction of a uterine tampon of gauze might prove serviceable. In discussing the advantages of intra-uterine styptics, Dr. Dakin omitted to refer specially to that excellent styptic and antiseptic, spirits of turpentine, which could usually be procured in any house; swabbing out the uterus with an aseptic sponge or cloth saturated with turpentine was the best way to apply it. In the employment of iron the same method, using a solution of 1 of liq. ferri fort. in 4 of water, was better than an injection of a weaker solution as mentioned by the author. But few cases would require much after treatment if due care in maintaining pressure over the uterus during, and for a time after the completion of, the third stage, was adopted as an invariable practice. Intra-venous transfusion could not be looked upon as a necessary part of the immediate treatment of post-partum hæmorrhage; for profound anæmia consequent on any great loss of blood it was a very valuable measure. If the patient was dying from bleeding this must be at once arrested, and then in a few cases transfusion might be advantageously employed. There was no advantage in carrying a mysteriously filled bag packed with gauze and a cumbersome transfusion apparatus when we could almost always, if not invariably, depend on the simpler, safer, and more efficient measures referred to previously by himself and other speakers in the debate. Practical midwifery owed much to that old Nestor of general practitioners Hamilton of Falkirk, whose practice in instrumental delivery and in the treatment of post-partum hæmorrhage had done more to revolutionise the art and save the lives of mothers and infants than seemed to be realised by many modern obstetricians.

Dr. **Herbert Spencer** had only once in 15,000 labours failed to check post-partum hæmorrhage from the placental site by the ordinary methods of emptying the uterus and compression and hot injections: that case he successfully treated with tampons soaked in solution of perchloride of iron. In a similar case he would now prefer to use iodoform gauze, though he thought it was with extreme rarity that it would be necessary to plug the body of the uterus. For hæmorrhage from lacerations in the cervix and vagina (which were often overlooked), he had repeatedly employed iodoform gauze or iodoform wool tampons, and considered them an excellent means of immediately stopping the hæmorrhage, and this treatment is far more practical than suturing the tear. For the collapse following post-partum hæmorrhage transfusion of normal saline fluid was very valuable. He believed he was the first to make a systematic use of this method of treatment (see *Lancet*, June 11th and 18th, 1894). He exhibited his transfusion-bottles and a wire clip which, with a piece of tubing and a cannula, enabled an irrigating apparatus to be improvised from an ordinary jug or bottle.

Dr. **Amand Routh** said that plugging the inert uterus with gauze arrested hæmorrhage most efficaciously, but not always by inducing contraction and retraction as the author implied. If it did so act, it would have to be explained why gauze excited the uterus to contract when other stimuli, such as the accoucheur's hand, had failed to do so. He had employed this method successfully on several occasions, especially after abortions, and he described a case of secondary post-partum hæmorrhage at full term, due to fright, where the uterus was distended and totally inert, and where the hæmorrhage ceased when packed with gauze, solely from pressure upon the placental site, as the uterus remained flaccid for several hours, and yet when the gauze was removed thirty-six hours afterwards, it wes found hardly blood-stained, though soaked with serum.

In reply, Dr. **Dakin** thanked the Society for receiving and discussing his paper. He thought that if a battery were handy and ready to work at once it might be worth trying, but it would be a cumbrous article to carry to every midwifery case. No doubt distending the uterus with a plug was contrary to physiology, but in his (Dr. Dakin's) experience the uterus had always contracted down quickly and compressed the gauze into a small mass, not allowing itself to be distended. As regards the admission of air into the vessels, this was a danger possible in all cases of manipulations in the recently emptied uterus at term, and could not be urged more against plugging than the injection of hot water. It was of course far better to get the uterus to contract without plugging it, by stimulation in other ways, and this had been advised in the paper. Dr. Boxall thought that water at 118° might paralyse the uterus instead of stimulating it. It was possible, but Dr. Dakin believed he had often had good results at this temperature, and if it were 118° F. in the douche-tin it would be less hot by the time it reached the uterus. Ergotin acted too slowly or not at all in very severe cases. In reply to Dr. Leith Napier, prophylaxis was not included in the scope of the paper, and the introduction of irritant drugs into the uterus had been mentioned. The speaker agreed with Dr. Spencer as to the rarity of severe post-partum hæmorrhage. The cases recorded were the only two which had occurred in the Maternity Department of St. George's in three years. Carbolic gauze was preferred because it was bulkier than other kinds when dry, and squeezed down when wet into as small a bulk as any. He was glad Dr. Spencer agreed with him as to the value of plugging being greater than that of suturing the cervix in cases where the hæmorrhage came from lacerations in that organ.

◆

LIVERPOOL MEDICAL SOCIETY.

Meeting held Thursday, February 15th.

The President, Mr. **Chauncy Puzey**, in the chair.

SPECIMENS AND CASES.

Dr. **Abram** showed a specimen of "Hæmorrhage into Pons Cerebri," the unusual features of the case during life being dilated pupils and subnormal temperature.

Dr. **Briggs** showed a "Uterine Polypi" which he had removed with scissors. The knob-like polypi was 4 inches in diameter, it lay in the vagina and was attached by a stalk 1¼ inches in diameter to the anterior surface of the body of the uterus. The symptoms had been (1) uterine hæmorrhage for two and a half years, and (2) a continuous watery discharge for twelve months.

Mr. **Hugh E. Jones** related a case of "Acute Suppurative Inflammation of Middle Ear, following Influenza," with some two months later extension of the disease through the vestibule to the posterior surface of the petrous bone, extra-dural abscess, caries of petrous bone, extension through petro-occipital suture, sub-occipital periosteal abscess; apparent rapid recovery after operation. Three weeks later purulent meningitis supervened. Trephining and incision of dura mater gave no relief. Death in three days.

Mr. **Banks** showed a case of "Excision of Hip for Old Unreduced Dislocation." Also "Some Cases of Excisions of Elbow and Shoulder-Joints." He insisted upon the importance of movement being commenced from the day of operation.

The **President** related the case of a young man who had recovered perfect movement of the elbow-joint after very severe injuries, including complete division of the biceps just above the tendon, paring of the divided ends, careful suturing having been followed by complete union. This patient it appeared had ten years before, when about 17 years old, sustained a rupture of the urethra, which had been left untreated, the result being that most of the urine was passed through perineal fistulæ. The opportunity was seized of treating the man for this condition as well as his wound. A curious condition of affairs was found (illustrated by diagram), and after two operations the man was sent home with a full-gauge urethra and a sound perinæum.

Dr. **Permewan** read a paper on "Some Points in Laryngeal Paralysis," referring in particular to Semon's law of the proclivity of the abductors of the cords to become paralysed before the adductors. Various explanations of this law are mentioned, and its general validity fully accepted. Attention was drawn especially to Zederbaum's experiments on the transmission of voluntary and reflex stimuli through a nerve trunk, and to the applicability of his results to the phenomena of laryngeal paralysis. Dr. Permewan also stated the great value of abductor paralysis as a means of diagosis in nervous diseases, particularly in locomotor ataxy, where paralysis of one or both cords is not unfrequently the first sign of the disease. He emphasised the fact that abductor paralysis may exist without any symptoms, and insisted on the importance of laryngoscopy in doubtful cases.

Drs. Hunt, Bark, Barr, Bradshaw, Abram, and Bickerton took part in the discussion.

◆

THE HUNTERIAN SOCIETY.

The Annual General Meeting held Wednesday, Feb. 14th.

The President, Mr. F. **Gordon Brown**, in the Chair.

After the Annual Report had been read and adopted, cordial votes of thanks to the retiring President Mr. F. Gordon Brown, the Vice-President, Librarian, Hon. Secs. were passed, and a ballot was then taken for the appointment of officers for the ensuing year; the scrutineers reported that the following officers had been elected:—

President—Charters James Symonds, M.S., M.D.; Vice-Presidents—John Poland, Henry J. Thorp, John S. E. Cotman, Peter Horrocks, M.D.; Treasurer—F. Charlewood Turner, M.D; Trustees—H. I. Fotherby, M.D., F. M. Corner; Librarian—Arthur T. Davies, M.D.; Orator—Patrick Manson, M.D., C.M., LL.D.; Secretaries—R. Hingston Fox, M.D., T. Horrocks Openshaw, M.S.; Council—F. Gordon Brown, James Galloway, M.D., Hope Grant, T. Mark Hovell, Francis R. Humphreys, Thomas Marshall, M.B., G. Newton Pitt, M.D., George W. Potter, M.D., F. J. Smith, M.D., R. G. Tatham, Alfred H. Tubby, M.S., John F. Woods; Auditors—S. H. Appleford, M.D., Francis R. Humphreys, R. Clement Lucas, B.S., F. J. Smith, M.D.

The meeting then adjourned to the theatre to hear

THE ANNUAL ORATION.

This being the anniversary of the birth of Hunter, Dr. Dundas Grant, as Orator of the Society, delivered an address on "Aspects of Medical Life, John Hunter and Andrew Clark." He compared the lives of the two men, and drew some interesting parallels between them—their nationality, length of life, uncertain health, work in the Royal services, untiring industry, accuracy in details, generosity, death in the midst of their work. The striking contrasts in the way of culture, courtesy, and acceptability were equally clearly brought out. The orator attributed much of Hunter's greatness to his allowing his original intelligence free play without the trammels of educational tradition, to his habit in youth of observing and studying natural objects instead of reading about them, but in a very large measure also to the teaching and influence of his highly cultured brother, William. Sir Andrew Clark owed much to having received a high-class education in surroundings, which, though not poor, were certainly far from luxury, and which fostered habits of industry, self-denial and devotion. The orator commented on the "dignity of the profession," condemning those who talked about and did nothing to maintain it, and recommended all who really valued it to study the lives and works of such men as John Hunter and Andrew Clark.

France.

[From our own correspondent.

Paris, Feb. 24th.

Cystostomy.

At the last meeting of the Société de Chirurgie, M. Lejars communicated four cases of patients with enlarged prostate on whom he performed the operation of cystostomy in the supra-pubic region.

The first case was that of a man, æt. 77, who entered the hospital with the following symptoms: acute retention, high temperature, tongue dry, respiration laboured, delirium, impossibility to pass a catheter, the bladder greatly distended. As relief was urgent, cystostomy was immediately performed. A vertical incision was made over the bulging bladder, and two needles of silk passed on each side to fix the organ; the bladder was incised as low down as possible, giving issue to two quarts and a half of strongly-smelling urine. The lips of the vesical wound were attached to the edges of the abdominal incision by means of sutures. The relief to the patient was very great, and his general condition improved rapidly. The patient left the hospital in a few weeks, his hypogastric meatus working regularly.

The second patient succumbed to advanced renal lesions. He was a stonecutter of 67, who for the last two years suffered greatly from difficult micturition and, had more than once to apply to the hospital. His prostate was hypertrophied, and although with some care a flexible catheter passed, yet an operation was considered necessary, as the urine was loaded with pus. Cystostomy was performed, giving issue to a pint of pus, which had filled all the *bas fond*. The local condition became much improved, but not so with the general state, which grew rapidly worse, and the patient sank. At the autopsy the two kidneys were found to be considerably contracted and full of cysts. The third man operated on was 68, very emaciated, and suffering from all the symptoms of vesico-prostatic trouble. After the first incision the operator passed in his finger to find the bladder; it came on a large irregular and hard mass, which turned out to be the bladder filled with calculi. Having fixed the organ to the parietal wound in the usual manner, M. Lejars removed by a large incision six large stones, which when removed permitted a good inspection of the parts. The mucous membrane was much inflamed, thickened, and bathed in purulent matter; the middle lobe of the prostate was hypertrophied.

After a good antiseptic washing out the wound was closed except in its inferior part, and the patient made a wonderful recovery: the urine flows freely through the artificial meatus and the man has regained strength and returned to his occupation.

The fourth case was not operated on in the same manner. The man, æt. 81, was not in a position to support chloroform, so a large curved trocar was passed into the bladder, over the pubes, and two quarts and a half of urine drawn off. A catheter was then passed through the trocar and left *à demeure*, to which was attached a long tube of caoutchouc, acting as a drain. The bladder was washed antiseptically twice a day, and the present condition of the patient is very satisfactory.

The Population of France in 1892.

Official statistics on the movement of the population in 1892 have just been issued. By them I find that during that year there were 290,319 marriages, 5,772 divorces, 855,847 births, and 875,888 deaths, or 20,041 more deaths than births. The foreign population, however, furnished an increase of 7,617 births over deaths. However, the English colony presented, on the contrary, 171 deaths more than births. That can be easily explained, however, by the fact that English families as permanent residents are very rare in France, and that many come only for a season for their health and are generally of a certain age.

Germany.

[From our own correspondent.]

Berlin, Feb. 23rd.

Lymph Cells.

At the meeting of the Society for Innere Medezin, of the 5th inst., Hr. Kossel gave an address on this subject. He said this subject has not only an interest as regards pathology, but also as regards the fact that the chemistry of the lymph cells furnishes us with a representation of the present position of the cells generally. We must, therefore, first of all learn to know the substances that play a part in these chemical processes. The chemical description must not be limited to an enumeration of the substances and a description of their properties, &c., but must also make clear the distribution of the materials and their relations to the anatomical elements. In correspondence to these points of view as regards the chemical constituents of the cells, two directions of investigation can be distinguished; the one seeks to isolate a larger series of eight cells, to take from them their peculiar constituents, and to make proof of their characteristics. The second direction has started from the anatomical considerations. The speaker has sought by the aid of the microscope and chemical reagents to determine the peculiar substances. For investigation in the first direction it is a necessary condition to isolate the largest possible number of cell elements in a state of the greatest possible purity. For this purpose chopped up lymph glands, especially thymus glands, have been used. They are subjected to pressure, and the juice is centrifugated. It can be ascertained under the microscope that the cells are well preserved. What now are the chemical constituents in these isolated cells? Amongst the large number of substances found in the tissue, there is a series found in every cell capable of development, the primary constituents of cells; albuminous bodies, lecithine, cholesterine, potass, phosphate (Hoppe-Seyler). To this series the speaker has to add nucleine. Along with these primary substances, there are a number of secondary ones not to be found in all cells capable of development: fats, glycogen, inosite, amidovalerianic acid. Amongst the substances named, nuclein takes the first place as regards quantity. In the lymph cells the whole nucleus is filled with nucleine. There are also certain combinations of nucleine substances with albumen molecules. Nucleic acid belongs to this group, a substance containing phosphorus. On examination of them, organic constituents are met with completely distinct from those of albumen. The speaker in his investigations has come to a knowledge of a series of cyclic carbon and hydrogen combinations resembling uric acid. These discoveries have led to the assumption that uric acid stands in a genetic relation to the nuclein substances, and the speaker believes, in fact, that he is in a position to prove this. Other atomic complexes are, present, however, besides those substances. The speaker found a very beautiful crystallising substance of very complicated constitution—thymine. But even with these substances the number of combinations from nucleine acid is not exhausted.

From those facts it is clear that along with albumen there are other peculiar groups of atoms quite distinct from it in a state of activity in the living cell. Nucleic acid is indispensable for the function of the cell nucleus, for it is constantly present wherever the cell is in a state capable of development. The notion according to which the albumen molecule is the carrrier of organic life is therefore incorrect. The speaker assumes an equally important *rôle* for nucleic acid. It is a remarkable characteristic of nucleic acid that it very readily combines with albumen. From nuclenic acid and albumen nuclein is formed. This, however, again attaches itself to another organic substance, nuclein is found in combination with an albuminoid body in the cell. The speaker found this albuminoid body ten years ago in the nucleated red blood corpuscles of the blood of birds and named it *histone*. This substance has been found in the cells of the thymus gland. Lilienfeld procured the combination of histone with nuclein in a pure state. Histone is by no means a simple albuminoid body. If the protamine from the spermatozoa of the salmon is combined with a solution of albumen and ammonia added, a deposit is formed which cannot be distinguished from histone. Histone can therefore be made artificially. On the other hand, however, the speaker has never succeeded in reducing histone into its constituents protamine and albumen. The reason for this is that albumen is capable of gradually uniting more firmly with the group to which it is combined, to take up the interior of the molecule and absorb it. Iron also by artificial manipulation of this kind may be firmly united to albumen, so that it cannot be extracted without breaking up the whole molecule. This freeing of the atomen complex from the albumen takes place in the cells apparently quite readily. In the young undeveloped spermatozoa of the salmon no protamine is present, only histone. In the mature spermatozoa protamine free from albumen can readily be demonstrated. The albumen attracts the acid colouring material, the nucleic acid the basic colouring material. Those combinations formed by the combination of nucleic acid with albumen have a mixed colour, i.e., a blue green. A freeing therefore of the nucleic acid may be concluded from the pure green colour of the constituents of the nucleus. The conditions under which the freeing of the nucleic acid takes place are not yet well known. The speaker has carried out a number of investigations in regard to the loosely attached nucleic acid in the tissues, and shown that the thymus cells are those organs of the body out of which nucleic acid is most readily obtainable. From the pancreas, for instance, no nucleic acid at all was obtainable. Some idea of the functions of nucleic acid will be first obtained when we have a more accurate insight into its chemical structure. For a physiological judgment, however, we have already some data. The speaker a long time ago made the observation that organic parts brought into combination with nucleic acid, became rapidly opaque and died off. He gave expression at that time to the opinion that the property of the acid might come into consideration as regards micro-organisms also. His brother has recently examined nucleic acid in regard to its bactericide properties, and shown that even in weak solution it kills micro-organisms with tolerable certainty. If a one per cent. solution of the acid is brought into contact with an equal volume of various bacteria their death can be determined. For the sake of comparison a similar solution of acetic acid was tried, and the nucleic acid showed itself by far the more powerful of the two. This bactericide action took place in an albuminous solution.

It is known that for a long time attempts have been made to obtain from cells a material that shall be responsible for their bactericide action. Nucleic acid possesses this property. We have no observation hitherto made that the cells actually use these weapons, but it may be assumed that they are not given them for ornamental purposes. Nucleic acid certainly plays a part in phagocytosis. There are also other substances in the cells with similar action, for the bactericide substances obtained by extraction from cells by earlier investigators are not at all related to nucleic acid.

From what has been said it is clear that chemical work on cells is in close contact with important problems in medicine. Hitherto indeed this work has exercised but little influence on cellular pathology. By the aid of the microscope the usual course of phenomena in pathological processes has been studied, how the cells change their form, &c., and by such anatomical observation an idea of the changes has been obtained, but a knowledge of the processes that take place is only obtainable when the question is approached from the chemical side. No one doubts that the living power that is put forth when the cell is irritated, comes from the chemical power, and the same holds good in regard to the toxines as well as for the formation of the antidotes. Problems of greater breadth have been thrown upon chemistry, but its means of aid are still meagre. These difficulties are, however, happily only external, and it is hoped they will soon be surmounted.

Vienna, Feb. 23rd.

Poliomyelitis Anterior Acuta.

Redlich read a long paper at the Club on the different theories propounded by eminent observors of the origin of this disease. Charcot attributed to an inflammatory affection of the ganglionic cells with a secondary interstitial change. A large number of observers considered the myelitis was located in the anterior horns of the cord. The opinions of Marie and Goldschneider are that the vascular system is the principal centre of the poliomyelitis. He showed a fresh specimen of a five months child where the changes of the anterior horns were associated with slight changes in other parts of the cord and where the vascular system had evidently been the primary cause. There were other circumscribed patches in the medulla oblongata, and in different parts of the cerebrum, where it seemed the circulation had carried the infecting materies morbi which presumably contained bacteria, and preferred as its *loco situ* the anterior horns as well as the other centres of the system, extending its influence also to some of the peripheral nerves where undoubted inflammatory phenomena occurred.

Intestinal Surgery.

This subject has now been before the *Doctoren-Collegiums* for several months. Hochenegg continued the discussion this week by recapitulating his own experience in this branch of surgery. He expressed his disfavour with the manner of irrigating the bowel by placing the patient on his knees and elbows and elevating the abdomen with bolsters. He recalled a case to mind where this caused sudden collapse, in another where a serious abscess gave way, the effusion setting up peritonitis and death. In this position you cut off two of the most important guides to avert impending danger, viz., the pulse and the appearance of the face. The irrigation for diagnostic purposes is best performed with a thick soft intestinal tube which may be passed high up without becoming entangied in any of the angular recesses. For therapeutical purposes one furnished with an olive end is best. The stomach should always be well cleansed and the neighbouring part of the bowel where fæculent vomiting is present. These precautions are necessary for after treatment, for if any fæcal matter be left in the bowel and paralysis produced by operation or pressure, the passage of the decomposing matter is arrested and auto-intoxication produced. He divides the operation into three groups—(A) Those where neighbouring morbid changes take place and press on the bowel, as ovarian tumours, fibroma, myoma, &c. Among these cases he related a removal of carcinoma from the liver, with small stones in the gall bladder which pressed on the bowel and totally occluded the passage. Four years have now passed since the operation, and no return appears imminent. Group B comprised those cases of hernia twisting and other displacements of the mesentery. He related two cases of duodenal twisting with fæculent vomiting while gangrene speedily set in. Another case was a man, æt. 46, who suffered from incarceration symptoms. The anal tube could not be entered more than 30 centimetres. In the operation a part of the bowel had becomes strangulated in the mesentery. The bowel was adjusted and retained with stitches, but the vomiting and constipation still existed. The wound being opened, the stitches were removed, and a large mass of offensive fæcal matter was passed. C comprehended cæcal tumours. These often entailed removal of a large portion of the bowel itself and bringing the ends together.

Dr. Telky next paraded his opinions, which he expressed in 1889, that less operative measures and more medicine would meet with more success in abdominal cases, and described many of these that had come under his own experience. One of them was a man, æt. 62, with intussusception, the other a woman with strangulated bowel around the pedicle of a tumour; all of whom were treated successfully with medicine. Goldhammer related 50 cases of intestinal occlusion, 15 of whom appeared in collapse before treatment commenced, but all were successfully treated without surgical operation. Another number of intestinal occlusions were intermittent, arising from chronic or late acute changes, which were certainly better treated by medicine alone. The most important drug in his armamentarium was opium given in large quantities, 0·03-0·05 of a gramme every hour or two, not exceeding 0·5 or 1 gramme per day. There seem to be different opinions about the quantity of water injected. Nothnagel tells us that a large quantity is dangerous, that it should not exceed 300 to 400 cubic centimetres, but he rather agreed with Oser in considering the quantity less than the position.

Gersuny could not understand how Tolky could altogether exclude operation any more than the surgeon excludes medical treatment. The injection of water was a surgical interference, and all important in rectal examination. Prof. Hofmokl disagreed with Oser's opinion that the fluid could not extend beyond the cæcal valve, for he could confidently point to three cases where this had been accomplished. There were symptoms in the diagnosis of these cases that were misleading.

He related two where the symptoms were perityphlitis, but was actually discovered to be duodenal ulceration.

Prof. Oser remarked that his experiments had all been tried on the dead body under severe pressure, and not one of them could be passed beyond the cæcal valve. In some of the cases where very little pressure has been applied, it has been found to pass. He believed in life under the influence of chloroform narcosis, cholera, &c., the valve is not closed, but in normal conditions it is closed. In a large number of morbid bowels the valve was not so close as to resist the upward flow of the fluid, and hence could be passed sometimes into the stomach, but as a rule it was very difficult to irrigate the small intestines.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Cholecystotomy.—Mr. **Anderson** operated on a woman, æt. 37, who had been suffering at intervals during the previous seven months with attacks of biliary colic associated with jaundice and other symptoms of obstruction to the flow of bile into the intestine. The suffering had been so severe that an operation was recommended. On examining the right hypochondrium there was an ill-defined dulness extending some distance below the margin of the ribs, but no special point of tenderness could be distinguished in the probable site of the gall bladder. A vertical incision was made along the right semilunar line downwards from the costal cartilages for the length of three inches. On opening the peritoneum the enlarged liver came into view, its edge reaching nearly three inches below the costal border. On raising this the gall bladder was felt contracted and containing calculi. With some difficulty the distal end of the gall bladder was fixed to the parietes, and, after packing the wound with sponges, the receptacle was opened and a facetted calculus about the size of a Barcelona nut extracted. Beyond this was a constriction of the gall bladder, and the canal was strongly flexed, but on passing a bent probe a second calculus could be felt at a distance of nearly three inches: attempts were made to seize this with forceps while it was fixed by the fingers of the operator's other hand within the abdomen. As it was found impossible to lay hold of the calculus, a scoop was introduced behind the stone, but the latter could only be withdrawn by tearing through the lower wall of the gall bladder. No other calculus could be felt. The wound in the gall bladder was then sutured, the mesentery being brought up over the sutured part and fixed with a few stitches. The wound was next packed, closed at its extremities. and dressed antiseptically. Mr. Anderson remarked, before the operation, that the diagnosis of the case appeared to be clear as one of biliary calculus, but that great difficulties might present themselves in the removal of the cause of the obstruction, several stones might be present, and some might be found to encroach on the common bile duct at a considerable distance from the surface, and in an area of considerable danger for operation. Should it be necessary to remove one of these deep calculi by direct incision, the suturing of the wound would necessarily present great difficulties, partly from mechanical reasons and partly on account of the lacerability of the gall bladder and its duct. If it be found possible to remove all the calculi by the distal opening of the gall bladder, the margins of the incision would then be fixed to the skin and the wound closed; in the other case the wound must be packed and left open with a view of giving vent to any possible leakage of bile.

ST. MARY'S HOSPITAL.

Cystic Tumour of the Lower Jaw.—Mr. **Norton** operated on a woman, æt. about 57, who had had a slowly increasing tumour of the lower jaw on the left side for nearly 20 years. He explained that the tumour, which was nearly the size of an orange, and at first sight apparently hard and bony, showed in some parts a crackling tendency of a bony case, and in two distinct places fluctuation, although very tense, as of two distinct cystic cavities. He concluded that such a tumour could in no way be malignant, but on the contrary, of a benign character, and composed of multiple cysts with bony septa and a bony case, which had probably arisen from the dental follicles. Mr. Norton said that in former years he had known instances of the jaw being removed in such cases, but it must be at once evident that it was of the greatest importance to retain the contiguity of the part, and, if the tumour could be removed leaving only a thin portion of the jaw-bone on the inside or the lower margin of the jaw, there would be afterwards a sufficient development of bony tissue to allow of the natural shape of the bone being retained and of its functions being carried out. An incision was made along the line of the lower margin of the jaw across the tumour an inch from the symphysis extending to within half an inch from the angle, the facial artery being at once cut through and ligatured; an elevator was next pushed around the surface of the tumour to free it from all soft tissues, the bony case was then perforated, opening up four or five cystic cavities, separated from each other by walls of bone. The whole outer bony shell was removed with the bone forceps, and the linings of the cyst cavities torn away, and the bony septa taken away by bone clippers. There now remained only the inner surface of the jaw-bone (which was not distended, but perfectly normal in shape in the mouth), and the lower border of the jaw which had been pressed down by the growth, and was considerably hypertrophied. The operator thought it well not to close the incision at once, but to plug the rough denuded surface of the bone with iodoform gauze until healthy granulations should be developed. Mr. Norton pointed out after the operation that there was no possibility of the return of the growth, that the strength of the jaw would not be diminished, and that it would differ from a normal jaw only in the lower outline; he added that he had seen cases in which cysts of a similar kind had been opened and plugged from the interior of the mouth, leaving the distended bony case intact; such procedure, he considered, would be almost invariably followed by an unsuccessful result, as the cavities would not granulate up, and considerable deformity would still remain; but in the case just operated upon there was only a surface of bone, which he anticipated would soon granulate and unite with the soft tissues in contact with it.

The Medical Press & Circular.

"Salus populi suprema lex."

WEDNESDAY, FEBRUARY 28, 1894.

"CELLAR" BAKERIES.

From time to time public attention has been drawn to the evils attendant upon the baking of bread in underground bakehouses, but without much practical outcome in the direction of legislative reform. There can be little doubt, nevertheless, that the intermittent protests of the press and the piecemeal efforts of sanitary administrators have had their value in educating the community upon a matter in which the welfare of every citizen is so closely concerned. Bread is an article of prime necessity, and its preparation, from the flour to the finished loaf, should be such as to render its quality above suspicion. But what are the facts of the case? If we are to believe Dr. Waldo, whose paper on this subject, read before the Sanitary Institute, will be found in another column, the conditions surrounding the preparation of bread in the metropolis and other large cities are such as to demand searching inquiry and reform. He estimates that on a moderate computation, at least one half of the total output of this staple article of food proceeds from "cellar" bakeries. His description of an underground bakehouse pictures a low, damp, basement room, lighted by gas, with rough floor, dank walls, and unceiled roof. In this place the flour is kept, the dough kneaded, the bread baked, and sometimes also stored. Sewer-gas may enter through the open floor-gratings or through the defective water-closet, which not infrequently stands in a corner of the cellar. Actual sewage may gain an entrance through a defective closet soil-pipe, or in times of heavy rainfall, in the low-lying districts, is forced back through the drain-pipes and floods the basement with sewage. As to the atmosphere which prevails in these underground bakeries, the words of the learned lecturer may be quoted. "Ventilation," he says, "in any real sense of the word, is absent, and, indeed, under the circumstances, is impossible. An inlet grating usually exists at the level of the street, but as a rule is kept carefully closed by the journeyman, who is morbidly susceptible to draughts. In most cases, again, there is another small inlet at the back of the cellar, but the second ventilator is almost invariably covered up by means of a sack. It will be seen, therefore, that not only is the air systematically poisoned from within, but also that no provision is made for that constant renewal from without which is essential to health. We may safely assert that no man could habitually work in an atmosphere even approaching that which has been portrayed without sooner or later sustaining serious injury to his health." The picture thus drawn is far from being a pleasant one to the bread consumer, although we are glad to know that possible objections are chiefly based on æsthetic grounds. But apart from æsthetic unpleasantness, there is a very great and serious injury inflicted upon the worker in these unwholesome cellar-bakeries by reason of his environment. As a class, journeymen bakers are unhealthy, they are especially subject to rheumatism, rupture, lung diseases, anæmia, flat-foot, together with liver and other affections of alcoholic origin. That they should be thus afflicted is easy to understand if we take into consideration the overwork, the long hours, and the unspeakably bad sanitary conditions which are almost invariably associated with the smaller bakeries. On the whole, we cordially concur with Dr. Waldo's opinion that there is no reason why baking, carried on amidst wholesome surroundings, should be a particularly unhealthy trade. The reforms he suggests are many. He would abolish underground bakeries altogether, and would insist on the storing of flour and of bread, the mixing and kneading and the baking, being carried on in separate rooms of a building specially constructed for the purpose. The sanitary conditions he would impose as to ventilation, drainage and water supply, may be summed up in the word perfection. He proposes to substitute, wherever possible, machinery in place of hand labour. These and other reforms he suggests should be considered by a Select Committee of the House of Commons. Meanwhile, those who take an interest in the onward march of sanitary science may be referred to the text of Dr. Waldo's paper, which will be found at length in another portion of the Medical Press. We are hopeful that the days of the cellar bakehouse are numbered, and that the paper in question may be found to have dealt a death-blow to a bad old system which has too long battened on the bodies of its workmen.

◆

THE CONJOINT EXAMINATIONS OF THE ROYAL COLLEGE OF SURGEONS, IRELAND, AND APOTHECARIES' HALL.

We understand that the attempt of the Irish College of Physicians to induce the College of Surgeons to withdraw from its conjunction with the Apothecaries' Hall of Ireland has failed, at least for the present. The Council of the College of Surgeons decided last week, after prolonged deliberation, to postpone further consideration of the subject for six months, which under the circumstances appears to be a very wise determination. This movement by the Irish College of Physicians, acting through the General Medical Council, does not claim the sympathy of the friends of high-class medical education in Ireland or elsewhere. It does not rise above the level of a cabal got up by a licensing body for the purpose of destroying a rival, and, if it had proved successful, it would not have added to the dignity either of that College or of the General Medical Council, by the method pursued to advance the desired purpose. In the first place, a general accusation of deficiency of curriculum and examination is made by the Representative of the College of Physicians, but the charge has never been formulated nor specified, so that the Apothecaries' Hall or its Committee of Management could meet such charge, nor does it appear that during the six years of working of the conjoint examinations a word of complaint was uttered by the College of Physicians or by anyone on its behalf until the conjoint diploma fee for the "Hall" was reduced to £26 5s, while the similar fee for the College of Physicians was retained at £42, whereupon a violent onslaught by innuendo and whisper was commenced against the conjoint examinations, and a semblence of reality was given to these whisperings by a notice of motion by the Representative of the Physicians in the General Medical Council. This question of diploma fee, though the most potential element in the controversy, is not one of which the General Medical Council can take any notice whatever, and we, therefore, need not discuss it at length. It is just, however, to say that if the fee for the conjoint (Physicians') diploma is maintained at an excessive amount, the fault lies altogether with the College of Physicians itself. Time after time the College of Surgeons has pointed out that the triple diploma of Scotland can be had by the Irish student for £26 5s. (and £10 10s. returned in case of failure), while the same student cannot obtain the analogous Dublin qualification under £42 (and nothing returned in case of failure). Time after time the College of Surgeons has offered to reduce its diploma fee, to meet this discrepancy, if the College of Physicians would reduce in the same proportion, and that College has persistently refused to entertain any such proposition. The Apothecaries' Hall, on the contrary, showed itself willing to make this or any other reasonable concession to the views of the College of Surgeons, and it certainly seems unreasonable that the College of Physicians should now claim to intervene to prevent the College of Surgeons from making, with another body, the bargain which the Physicians themselves refused. However, a difference of £5 5s. in a diploma fee is not, we believe, a matter upon which the College of Surgeons would think it worth while to maintain a quarrel with its partner, and if the reinstatement of the fee at its original amount would restore harmony, we imagine it would be readily done. But there is much more than this. It is notorious that ever since the College of Surgeons entered into its conjunction with the Apothecaries' Hall the College of Physicians (we should rather say the dominant party in that College) have adopted a supercilious demeanour towards the College of Surgeons and have continuously withheld that cordial co-operation which was necessary to the harmonious and successful working of the conjunction. Complaints have, for the last six years, been loud and frequent that the terms of communications from the Physicians to the Surgeons have been, usually, scarcely civil, and that almost every suggestion from the College of Surgeons, even on matters of trifling detail, has been met by the College of Physicians with an unsympathetic *non possumus*. It is but recently that the Council of the College of Surgeons convened what it was hoped would have been a friendly conference to discuss, verbally, certain proposals which it had been found impossible to settle amicably by official correspondence. Every one of the suggestions of the Surgeons was received by the Physicians' delegates with the customary curt *non possumus*, and the conference resulted in nothing. The Fellows of the College of Physicians who insisted on its adopting this attitude towards the sister College could scarcely hope that the College of Surgeons would be willing, by cutting adrift the Apothecaries' Hall, to place its future unreservedly in the hands of a body which, for six years, had manifested a spirit of contemptuous ill-will rather than one of cordial co-operation. It will be recollected that the General Medical Council, at its last meeting, was induced by the College of Physicians to fulminate a threat that it would extinguish the Apothecaries' Hall conjunction if additional courses of lectures in mental disease, vaccination, biology, physics, and ophthalmology were not at once imposed upon its candidates. We may say, at once, that this order has been already complied with, but complied with, we believe we may say, under the unanimous protest of both the College of Surgeons, the Apothecaries' Hall, and every one concerned. We believe that it would be difficult to find amongst the Dublin teachers or hospital surgeons (outside those interested in the course to be imposed) three men who consider the imposition of these courses, especially those on mental disease and vaccination, to be anything but an incubus the imposition of which is unfair to the student and neither necessary nor expedient from an educational point of view. The Irish College of Physicians knows well that the College of Surgeons have been consistent in resisting the addition of these courses in the Physicians' own conjoint scheme, and that it gave way to the College of Physicians, as it has now given way to the General Medical Council, not because it was convinced that these courses would be of any use to the student, but because it could not help doing so. As to the alleged deficiencies in the apothecary's examinations, it must be admitted that, as reported by the Visitors, the medical side of the examination was bad; the Apothecaries' Hall has been the first to recognise that fact by making the necessary changes in the examining staff. Nothing, however, can afford clearer proof of the spirit which has animated the College of Physicians and its supporters in this controversy than the avidity with which they have fastened on this detail for the purpose of squelching the Apothecaries' Hall. We do not consider the negligence or incapacity of one or two examiners, even if proved, as a sufficient reason for condemning an entire scheme of examination or demanding that it shall be extinguished, nor are we prepared to accept the opinion of any two Visitors from the General Medical Council, however respectable, as finally conclusive that a scheme of examination is bad beyond recovery. If we regard such opinions as final we should be driven to conclude that the examinations for the medical and surgical degrees of the University of Dublin, which were declared a few years since to be "insufficient," ought to be expunged from the list of registrable qualifications, and that we should demand that the General Medical Council should now perform its duty with strict impartiality by advertising the hostile verdict which it passed upon the conjoint examinations of the College of Physicians itself with as much alacrity and with as full publicity as it has given to its condemnation of the Irish Apothecaries' Hall. We shall certainly not lend the influence of the Medical Press to sustain any scheme of curriculum or examination which is not *bonâ fide* and efficient; neither shall we stand by and see the Apothecaries' Hall, which has, we believe, tried to do its duty as a licensing body honestly and to the best of its ability, sacrificed and discredited by a collegiate faction.

◆

Notes on Current Topics.

The Notification of Tuberculosis.

The Cheshire County Council has just issued an order to all the sanitary authorities within its district directing the latter to add phthisis to the list of notifiable diseases under the Notification of Infectious Diseases Act. There is nothing very new in this, despite the excitement which it seems to have caused among certain of our lay contemporaries. In several States, for example, in America, the notification of phthisis has been for some time enforced by law. On the Continent, moreover, generally, the infective nature of tuberculosis has for long been recognised very much more extensively than is the case in this country. A morning contemporary is quite in error in supposing that "there is considerable room for doubt that consumption is infectious," or that "we know very little that is not purely negative about the mode of propagation of this mysterious disease." There is no mystery about tuberculosis; its mode of dissemination is quite understood, but, because the character of its infectivity differs from that of the exanthemata, the laity should not suppose that nothing is known of its infective qualities, or that modern science has been unable to divulge the means by which it is propagated. Although, perhaps, phthisis is scarcely a disease which should be included among those notifiable under the Act, nevertheless, there is much reason for the belief that, were more stringent measures of prevention adopted, especially among those whose family history points to a predisposition to the disease, a sensible reduction in its mortality would quite possibly be the result. The statement that the death rate of printers from this cause is nearly more than twice that of average members of the community is explainable on several grounds, but mainly, in all probability, by the confined nature of the occupation and the crowding of the workers.

Brain Surgery in Japan.

The benefits of modern surgical science have, through the enterprise of members of the medical profession in Japan, been brought within the reach of dwellers in that Oriental region. In proof thereof, attention may be drawn to an interesting case of brain surgery which is reported in the current number of the *Sei-i-Kwai* medical journal. A farm labourer, æt. 47, received a lacerated wound of the scalp, over the left parietal region, associated with, as was afterwards shown, a depressed fracture of the skull in this situation. The wound healed in the course of a month, leaving paralysis of the right lower limb. Dr. S. A. Miyake, the surgeon under whose care the patient came, twelve months after the injury, decided to trephine the skull over the seat of the injury. Accordingly, when chloroform had been administered, he operated as follows:—"I cut," he says, "a skin flap of oval form and raised up a thin layer of bone with the periosteum by means of a flat chisel, and then found two lines of bony fissure crossing each other. After applying a small trephine I found that the depressed portion of the parietal bone was three times as thick as usual, pressing down the cortex of the brain. As one trephining was not sufficient, on account of the extent of the indurated bone, I trephined thrice, and thus made a large clover-leaf-shaped perforation, and cut off the projecting points of bone with Luer's forceps. The bone adhered to the dura mater only at a small part near the longitudinal sinus, while at all other parts the dura mater was healthy. Blood escaped freely from the adherent part, but the flow was readily arrested by means of a cotton tampon. The skin flap was replaced, no sutures were applied, and a bandage which had been previously sterilised in the disinfecting apparatus of Schimmelbusch was put on." The wound healed in about three weeks, and by that time the recovery of power was very marked. The trephined space became almost as firm as the normal skull, which result was attributed by the author to the new formation of bony tissue pressing down the thin piece of bone which was separated with the periosteum. After two months' interval, subsequent to the operation, the report was that there was hardly any difference between the muscular power of the two limbs.

Professors of Physiology as Executioners.

The Legislature of the State of Ohio have now a bill before them which can be said to be distinctly novel. It is one for the purpose of substituting physiological experiment for capital punishment, and its first clause runs as follows:—"That all persons sentenced to death by any court having jurisdiction in the State of Ohio shall be held as subjects for experimental research; that such experiments shall be conducted in the interests of science and society, and shall be regulated by approved rules of humane treatment to avoid all unnecessary pain; that in the preparation for such experiment, where pain would be occasioned, anæsthetics shall be administered to the extent of complete insensibility to pain, and during the progress of the experiments narcotics shall be used to allay pain, and the condemned person shall not be maltreated in any way; that after the conclusion of such experiments the criminal shall be again anæsthetised and put to death while in a deep sleep; that the executioner shall be an expert physiologist duly appointed and authorised by the State, and that the executioner's staff shall consist of himself and five assistant physiologists with a like number of deputies who shall hold their office for the term of good behaviour except upon proof of incompetency. . ." The bill also contains two other clauses regulating the place of execution, and the conditions under which persons will be entitled to witness the ceremony. Who can have been responsible for this remarkable effort at legislation? Whose ingenuity was equal to framing such an extremely novel bill? To discuss the matter seriously is out of the question, not because we do not consider that a man who has been convicted of a brutal murder by a jury of his countryman has forfeited his life to the State, and is deserving of a legal violent death, but because it is certain that the proposals such as the bill contains would be warmly condemned by popular sentiment.

Does Tobacco-smoking interfere with Growth?

THE latest inquiries respecting the effects of tobacco-smoking upon physical development display to a still greater extent the perniciousness of the habit in young life. Dr. Hitchcock of the Amherst College, U.S.A., found that of the students in the year 1891, 75 per cent. increased in their measurements during the whole course, while 29 per cent. remained stationary or fell off. In separating the smokers from the non-smokers, it appeared that in the item of weight the non-smokers increased 24 per cent. more than the smokers, in height they surpassed them 37 per cent., and in the chest girth 42 per cent. Lastly, in the lung capacity there was a difference of 8·36 cubic inches (equal to about 75 per cent.) in favour of the non-smokers, which was 3 per cent. of the total lung capacity of the class. Dr. Hitchcock, guided by these statistics, would doubtless advise young people not to smoke, and with such advice we entirely agree, though we can scarcely help expressing the fact that if Dr. Hitchcock had been a smoker he would have collected statistics in another year and found the strength of evidence on the other side.

A Valuable Appliance.

A SHORT editorial comment appeared in the last issue of the MEDICAL PRESS AND CIRCULAR. It dealt with a puffing notice published in a ladies' paper in praise of an apparatus which claimed to cure a number of diseases by the generation of oxygen. Curiously enough, the current number of *Science Siftings*, one of an increasing class of modern journals which devotes its energies to the exposure of quackeries, contains an article upon this very appliance. Our contemporary has had the advantage of a personal investigation, and as his remarks emphasise our suspicions, some of the salient points of his article may be noted. The writer states that the apparatus consists of a nickelled metal cylinder about three inches in length by one inch in diameter. This cylinder is loaded with plumbago and sulphur, and carries about twelve feet of scarlet cord, at the end of which is an elastic loop capable of being used as a wristlet or anklet. The price of the appliance is five guineas, a considerable advance on the estimate of a well-known fancy goods dealer in the City of London, who says: "If this article were amusing or useful I would price it in my establishments as a shilling line." It is obvious that the apparatus as above described could not generate any known force, electrical or chemical, there being but one attachment to the cylinder. Yet the proprietors of this instrument claim that it is able to cure such diseases as diphtheria, locomotor ataxia, as well as heart disease and consumption. They publish a pamphlet describing the many virtues of the appliance, and quoting a number of favourable press notices and the usual list of testimonials from clergymen and others. The editor of the journal from which we have quoted throws down the gage at the end of his article in the following passage: "To pretend that diphtheria, cancer, or heart disease can be cured by wearing an elastic wristlet fastened by a cord to a piece of metal is surely criminal, when the pretence is made with intent to obtain money."

Guardians and Notification.

ONE of the members of the Hitchin Board of Guardians has secured a committee of inquiry into what he calls "gross overcharges" in reference to the notification of infectious disease. His contention was that a medical man received his half-crown fee for notifying the existence of an infectious disease in a house, and that he was not entitled to make a separate charge for each patient therein. In looking through the accounts he found that in many instances notification had been made of three, four, and even five cases in one house. If fifty cases occurred in a school, he asked, was the doctor to charge 2s. 6d. for each child thus attacked? We may reply that, whatever opinions may have been formed of the beneficence of the Act, the principle which, rightly or wrongly, underlies it is to give sanitary authorities the power of following up affected *individuals*. A mere general knowledge that a particular kind of fever was abroad in his district would not afford a medical officer of health very material help in stamping out an epidemic. Again, would the guardian in question wish to render other certificates collective? Would he, for instance, accept a single certificate that the children of John Smith's family had been efficiently vaccinated? or that fifteen scholars of a certain school had died of small-pox, and might be buried forthwith? He has persuaded the Hitchin Guardians, however, to memorialise the Local Government Board on the subject.

Huxley and Tyndall as Poets.

PROFESSOR HUXLEY and his late friend Professor Tyndall have won a world-wide fame as men of science; their claim to be considered as poets, however, is not by any means so well recognised as Mr.

Jonathan Hutchinson would have us believe. The latter distinguished surgeon lately impressed on an audience at Haslemere his admiration for the poetic talents of the distinguished scientists in question. No doubt both Tyndall and Huxley have displayed a vein of vivid and attractive imagination in much of their best work, but that is a very different thing from possessing the rare gift of poetry. Truth to say, the published verses of both these distinguished men are of a commonplace and inartistic order, and neither could hope to gain any portion of the bays which a complaisant Parnassus sometimes awards to very minor poets.

The Coombe Hospital Scandal.

The pathetic melodrama of the vindication of the outraged feelings of the late Master of the Hospital against the stage-villain aspersions of the *Dublin Independent* came off on Tuesday last. Dr. Hoey valued his feelings at £3,000, the *Independent* at *nil*. Eight barristers and two firms of solicitors and a host of witnesses, medical and other, were ready for the fray, when, to universal disappointment, the affair resolved itself into the usual interchange of civilities, with the Bench to see fair and the clients to pay. In due course the leading counsel for Dr. Hoey said that his client was deeply injured, and would deny on oath that he ever performed an illegal operation on the deceased matron, which was quite unnecessarily done. Leading counsel for the newspaper then, as arranged by the stage manager, said that the aspersions were in a Pickwickian sense, and, if understood otherwise, they were unreservedly withdrawn. The judge then conferred his blessing upon the lawyers and the litigants, and ordered the *Independent* to pay £40 and costs. The barristers withdrew their cheques from the folds of their briefs and the solicitors went back to their offices to compile their little accounts, and thus ends the Coombe Hospital scandal, as far as law is concerned. Let us hope that the disgraceful mismanagement and jobbery, political, religious, and personal, which brought the hospital to the verge of dissolution will be as readily and as pleasantly terminated, and that the new Master will be given a free hand to re-organise and restore the hospital to usefulness untrammelled by the enmity and bigotry of contending parties on the Board of Governors.

A Veterinary College for Ireland.

The Chief Secretary for Ireland has, in response to the representations made to him by an influential deputation, written to Dr. C. J. Nixon, who may be regarded as the promoter of the scheme, to say that the Government will be prepared to grant £15,000 towards the establishment of a Veterinary College in Dublin. The project has been talked of for a great many years, the late Dr. Lyons, M.P., having taken much interest in it, but it never assumed a practical condition until now. Considering the great importance to Ireland of maintaining its trade in horses and the supremacy of its breeds, it would be difficult to find a direction in which £15,000 could be more usefully expended than in the establishment of such a college, and we believe there exist amongst the veterinary surgeons of Dublin many men very competent to organise and carry on such an institution. We regret to observe that one or two veterinary surgeons in Dublin have allowed themselves to be "interviewed," and have expressed themselves as adverse to the scheme. This, we opine, means that they consider they were not given a sufficiently prominent position in the deputation and other preliminary negotiations, for which reason they denounce the movement as a "doctors' job." We do not exactly see what the doctors are supposed to gain by the establishment of such an institution, and we rather think that the promoters will be only too glad if the veterinarians will take the matter in hand and work up the establishment for the advancement of veterinary surgery and pathology in Ireland in their scientific aspect.

The Action for Injunction against the Medical Defence Union.

Mr. Justice Chitty gave judgment in the case for injunction against the Medical Defence Union last week, the result of which affects very closely the members of the Union. The facts of the case, which are of an unusual character, were fully reported in our last issue. Briefly, a dispute arose between two medical practitioners, Dr. Bloxham and Dr. Collie, in respect to a partnership agreement, both being members of the Union, and the injunction was brought by the former to prevent the Union from taking up the case for the latter in the impending action between the two disputants, the Union having previously refused to render assistance to Dr. Bloxham. In giving judgment Mr. Justice Chitty held that, on their proper construction, the memorandum and articles of association were wide enough to justify the action of the Union. In his view the Union possessed the power which it had exercised; the action originally taken by its Council had become that of the Union itself by force of a resolution at a general meeting. The suggestion that the conduct of the defendant Union amounted to "maintenance" was, unfortunately, made without due notice to the other side, and the judge consequently declined to give any decision in regard to it, but pointed out that if the defendant Union had committed this offence, the plaintiff had his remedy by an action at law. We were under the impression that a resolution had been passed at one of the annual meetings of the Union that no questions of disputes between medical men involving legal proceedings should be dealt with by the Council. Has this ruling been departed from in the present instance?

A Medical Libel Case.

We understand that a libel case which is likely to arouse more than passing interest in medical circles is about to come before the Court of Queen's Bench as a result of some letters written on the occasion of the recent election of a medical officer by the Woolwich Guardians. The plaintiff is Dr. Logie, who pursues Dr. Maxwell for £4,000 special damages. Both gentlemen are practitioners at Woolwich.

Anti-Vaccinationists at Weston-super-Mare.

Mr. Walter Robert Hadwen, L.R.C.P. Lond., L.S.A., 1893, Highbridge, Somerset, was, according to the Medical Directory, a student of the Bristol Medical School and of St. Bartholomew's Hospital, London, and yet, despite the presumably good influences in medical training with which he was brought into contact at these two medical schools, he no sooner obtains his qualifications than he becomes an anti-vaccinationist of the most virulent type. At a public meeting held last week at Weston-super-Mare, called for the purpose of expressing sympathy with two men who had been imprisoned for wilfully refusing to comply with the Vaccination Act, he is reported to have said: "I am delighted to find such a bold stand being made against vaccination in Weston-super-Mare. I hope you will stick to your guns, for vaccination is not only a superstition, but a cruel blot on the statute book. Vaccination is not only useless, but is calculated to produce serious consequences, and, if this is so, which I am prepared to prove, the sooner it is swept from the statute book the better." This newly-qualified, and, we suppose in his opinion, enlightened member of the profession, further informed his audience that vaccination, because being a superstition, was a relic of the past, and that doctors in their training were taught nothing about vaccination. But this was a very lame argument for Mr. Walter Robert Hadwen to have advanced in excusing himself for adopting the anti-vaccinationist propaganda. Inasmuch, however, as he only qualified last year, it may be anticipated that with a little longer acquaintance with medical practice he will have opportunities of witnessing the good effects arising from the beneficent law which he condemns, and of thus being induced to admit the absurdity of his opposition. Meanwhile, as was the case with Mr. Allinson, it would be well for the General Medical Council to take note of this new medical anti-vaccinationist.

Amalgamation Projects.

There is a current of amalgamation in the London medical world, which gives evidence of its presence from time to time. First, there was the proposal to amalgamate all the reputable medical societies of the Metropolis into one homogeneous academical whole on special and peculiar terms in that after conjunction they were still to be separate. In fact, the scheme was strongly suggestive of a marriage *avec séparation de corps et de biens*. This scheme, which, in spite of its incongruity, had much to recommend it, was a subject of interest to the late Sir Andrew Clark, and since his regretted demise it seems to have lapsed. For months past we have been worried with proposals, counter-proposals, and recriminations in respect of the amalgamation of the Medical Defence Union with its junior rival, and while the presidents of the respective societies sit looking contemplatively at each other like two china dogs, the luminous idea has occurred to our contemporary the *Medical Times* to propose that the two contending factions should seek repose and peace in the bosom of that bantling, the Association of General Practitioners. The naïve suggestion is added that the *Medical Times* might be made the official organ of the trinity with advantage to all concerned. Our contemporary will doubtless next suggest some scheme of amalgamation with the Royal Society on similar lines —and with as much prospect of success.

Rabies, Cause and Effect.

We read that rabies has been "alarmingly prevalent" in Glasgow. The "alarming prevalence" is represented by three persons having been bitten by a dog which was "secured and destroyed" and one other by a dog "supposed to be suffering from rabies;" the "post-mortem appearances were suggestive of rabies"—whatever that phrase may mean—and the sufferers were at once despatched to the Pasteur Institute in Paris, while the Glasgow magistrates at once issued a muzzling order. At the meeting of the Health Committee, Dr. Colquhoun protested against the sending of persons bitten by presumably mad dogs to Pasteur's Institute at the public expense, but his objection was overruled. If the fact that four persons snapped at by a dog "supposed" to be rabic is sufficient to get up a craze for muzzling, the sooner that process is made permanent and not perfunctionory the better. The existing system of fright and flurry is calculated to cover the law and the magistrates with ridicule.

Port Sanitary Administration.

It is well known that England stands high in the estimation of Continental nations as regards her practical sanitation. This fact has been further illustrated by the visit of two Hamburg officials, who have been despatched to this country in order to make themselves acquainted with the details of port sanitary administration, and to study the question of sewage purification. The two officials in question are Dr. Nocht, the Principal Medical Officer of Health for Hamburg, and Herr Meyer, the leading Engineer of Public Health. It is their intention to make the round of all the principal English ports. Our sanitary authorities have in late years succeeded in excluding cholera from the seaports, but this has probably been effected by rigorous attention to the drinking-water supply, a point in which Hamburg, judging from recent accounts, appears to be specially defective. The visit of these distinguished officials on such an errand is a compliment to England as a leader in practical sanitary matters.

Allinson versus the Medical Council.

In another column will be found a report specially taken in court for this journal, the points raised being of considerable importance to the profession, and the decision therein given being absolutely without appeal. While we feel that no comment of ours upon the judgment is called for, we cannot refrain from expressing our amazement at the character of the ideas respecting the merest elements of physiology which apparently are entertained by the author of the "wipe the arm" suggestion. We sincerely trust that the scientific advocates of vegetarianism (who, by the way, include some of the clearest thinkers and hardest workers in each of the several ranks of our profession) may not be supposed to be besmirched by any of the references that have been made in the course of this case. And we may fairly ask, when will the gullible and, to a large extent, the mulish public, begin to recognise the abject folly of those persons (innocent of all necessary knowledge) who profess to diagnose *non-existent* internal disorders by means of what they, in their offensively-obtruded ignorance, pretend to regard as infallible signs? Of such are the providers of the material out of which the "miraculous cures" are manufactured. One is almost driven to the opinion that the British public *deserves* to be handsomely fleeced by the electrical, humbugging, and advertising quacks, and by all sorts of practitioners "infamous in a professional respect."

Dr. Butler-Hogan, in October last, was elected Medical Officer of Health for Shoreditch by a considerable majority. Owing, however, to an informality on the part of the Vestry respecting the amount of salary, the Local Government Board annulled the election, and a new one, consequently, has to take place.

Dr. Pye-Smith will deliver this evening (Wednesday) the first Huntarian Society lecture of the current year at 8.30 p.m., at the London Institution, Finsbury Circus. The subject selected is "Rational Therapeutics," and the lecture will be open to all members of the profession.

Mr. Herbert William Page, F.R.C.S., Surgeon to, and Lecturer on Surgery, at St. Mary's Hospital, has accepted the invitation of the Council of the Harveian Society to deliver the Harveian Lectures next Session. He has chosen an important subject "Some Disorders of Nervous Functions due to Injury and Shock."

We understand that the subscriptions to the proposed memorial to the late Professor Marcus Beck have come in so well, that the Treasurer, Mr. Christopher Heath, has been able to hand over to the Committee of University College Hospital the sum of £800 to endow a bed in memory of the deceased.

The Local Government Board has sanctioned the proposal of the Merthyr Local Board to increase the salary of their medical officer from £250 to £300 per annum, such increase to date from January 3rd last.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Morrison Lectures on Insanity.—In Dr. Batty Tuke's fourth lecture, delivered last week, mention was first made of the fact that in persons dying insane the naked eye manifestations of disease were not so marked in the anterior lobes, the supposed site of the psychical processes connected with the higher intellectual functions, as in the Rolandic sensori-motor areas, and that therefore the transformation of stimuli into motor acts was not the only function of these areas, storage and transmission of impressions being added, interference with which caused the so-called "mental" symptoms. After various forms of cerebral degenerations were described, the lecturer proceeded to lay stress on the wonderful delicacy and complexity of the brain substance and on its comparative freedom from traumatic injuries, due to the elastic cushion provided for it by the cerebro-spinal fluid, on the normal ebb and flow of which, also, the brain health in no small degree depended.

Edinburgh Royal Infirmary—Details of Maintenance.—An interesting paper has just been issued giving short details of the medical expenditure and cost of maintenance per bed during the last 25 years. The figures with regard to both subjects are instructive as showing the change in feeding and treatment which has occurred during that period. For instance, under the heading of medical expenditure the average cost per bed for the five years ending 1878 and 1893 respectively for wines has fallen from 8s. to 2s.; for spirits, from 9s. to 8s. In 1893 itself the cost per bed for wines fell to the very low figure of 1s. Little change has occurred in the cost per bed of medicines and dressings, while incidental expenses have risen over £1, the total average cost being about £1 more now than 20 years ago. In the details of maintenance we find bread now costs per bed £1 less, meat £3 less, milk £2 15s. more, the total cost being very nearly £2 less all over. It is interesting to note the large increase in the quantity of milk consumed instead of bread and meat, although, of course, some of the decrease in the cost of the latter articles is due to their prices being lower. In another table it is shown that in 1874-78, with 444 beds occupied, the total expenses were £53 9s. 5d. each year on an average, while in 1889-93, with 654 beds, they reached £61 3s. 5d.

Fever Hospitals.—In a report of the sub-committee of the Leith Town Council anent the proposed Fever Hospital for the Burgh the erection of a brick building with four ward blocks was unanimously recommended, the whole to cost about £30,700. It has also been proposed to erect a hospital for the reception of patients suffering from infectious diseases at Paisley, and in connection with this Dr. Archibald Donald, Medical Officer of Health for the Burgh, was consulted as to the suitability of the present Infirmary buildings, a new site having been bought for that institution by its directors for a fever hospital. In Dr. Donald's reply he deprecated the purchase of the Infirmary buildings, on the ground that, as they stand, they would require much alteration even before the necessary permission to occupy them as an infectious diseases hospital could be obtained, while they would only satisfy the demand for a few years to come. With regard to the site, he recommends the erection of a hospital in a suburban district, far from surrounding houses, with sufficient space for the patients to take outdoor exercise when convalescent. The local authority on receiving this report decided not to purchase the site of the present infirmary.

Small-pox in Edinburgh and Leith.—Cases of small-pox still continue to be reported both from Edinburgh and Leith during last week for instance, five cases were discovered in Leith; and four in Edinburgh.

Sir Joseph Lister to Visit Glasgow.—The arrangements for the meeting of medical students of the Glasgow University to be addressed by Sir Joseph Lister have been completed. The address will be delivered in the Students' Union on Thursday, 8th March.

Queen Margaret College.—An interesting function in connection with this college is the Hon. Secretary, Miss Galloway's monthly "At Homes." At the last, on a recent evening, there was quite a galaxy of professors and students to witness a delightful performance of "Mrs. Willis's Will," followed by an enjoyable dance and music.

Correspondence.

THE MEDICAL DEFENCE UNION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Permit me to correct a slight error in your report of the annual general meeting of the Medical Defence Union on the 7th inst. with reference to the action of Council on the proposed amalgamation with the London and Counties Protection Society. A resolution proposed by me was carried, to use the President's term, *nem. con.* I do not recollect the exact wording, but the resolution was of the following purport: "This meeting trusts that the Council will feel enabled to resume negotiations for amalgamation with the London and Counties Protection Society."

In every such negotiation hitches are inevitable. Both Councils have, I believe, acted with the best intention, and have failed to arrive at success; but the waste of power and finances from two societies, with separate staffs, doing the same work of medical defence, are too serious to finally abandon the now lapsed effort at union without another effort.

I am, Sir, &c.,
Norman Kerr, M.D.

42 Grove Road, London, N.W.,
Feb. 22, 1894.

[Our report stated that there was no time *to discuss* the proposed amalgamation. Dr. Kerr's resolution was carried practically without discussion.—Ed.]

◆

Obituary.

PROFESSOR LEISHMAN, OF GLASGOW.

We regret to announce the death of Professor William Leishman, Emeritus Professor of Midwifery of the University of Glasgow. His death took place on Sunday the 18th inst., at Blairmore, Loch Long. Although Dr. Leishman's retirement from the Chair in the University was only officially announced a few months ago, he had not been in harness for a period of nearly two years, his temporary retirement being brought about by a brain affection (hemianopsia). It was thought, however, that he had the prospect of some years' leisure before him, being only in his 61st year of age. Unfortunately, at the beginning of the week previous, a change took place for the worse, and he gradually sank. The deceased was the second son of the late Dr. Leishman, of Govan, and a distinguished graduate of the Glasgow University, and while still a young man was requested to join the staff of Anderson's College, and one of the physicians to the Glasgow Royal Infirmary. After the death of Professor Pagan, the then Professor of Midwifery in the University, Dr. Leishman was appointed by the Crown to the chair in 1868. In all his public appointments his duties were discharged with thorough earnestness, and when moved to speak in public he did so in a manner that commanded attention and respect. In the Royal Infirmary his clinical classes were always crowded, his lectures being unsurpassed, and his bedside teaching was clear, concise, and thoroughly scientific. His funeral took place on Thursday the 22nd inst., the remains being interred in the family burying ground in the Govan parish churchyard. Principal Caird conducted the funeral service. Most of the University Professors were present.

◆

Literary Notes and Gossip.

The value and number of scholarships in the University of Aberdeen are to be increased by the addition of the Anderson Legacy of £5,000. This welcome amount has been bequeated by the late Miss Anderson for the founding of one or more scholarships at the discretion of the University Court.

⁂

Of the 234 medical journals published in the United States, Ohio has fourteen, New York fifty-two, against eight in London. Of 1,260 medical societies in the United States, Ohio has ninety, New York one hundred and seventy-five. In London we have only about forty, and these are considered too many.

⁂

The February number of the *English Illustrated Magazine* well maintains the excellent standard for readableness and variety of subjects which now distinguishes this periodical. There is an appreciative article on "My Impressions of Zola," by Mr. George Moore, embellished with many excellent illustrations, together with an autograph letter of the well-known novelist, and a very chatty and characteristic contribution on the "Zoo," by Mr. Phil Robinson. There are many other papers of fiction and fact. Altogether, this magazine is fast becoming one of the best sixpennyworth's of the kind now extant.

⁂

The literary tastes of Mr. John Morley have apparently undergone no diminution since his withdrawal from the active pursuits of journalistic life, for it is stated that he finds time in the midst of his official work in Dublin to peruse catalogues of old books dealing with Irish history, and to make a selection of the most attractive for purchase. He is also keenly interested in the historical associations of the Dublin public buildings, and has expressed his pleasure on being assured that the very room in which he transacts the official business of Chief Seretary was used for a similar purpose by Lord Castlereagh.

⁂

The March number of *The Humanitarian*, Mrs. Victoria Woodhull Martin's magazine, contains among other articles one on "The Progress of Pharmacy," by Dr. Lauder Brunton. It is instructive and interesting, and Dr. Brunton says some funny things about the common or garden toad, and its toxic qualities. "It is quite possible," he admits, "that some of these days we may have an enterprising firm advertising essence of toad as being of superlative virtue for the cure of dropsy." And then we should have "toad-farms" springing up all over the country as a new commercial industry.

⁂

The *Indian Medico-Chirurgical Review* for January publishes *in extenso* the Presidential Address delivered at the annual meeting of the Grant College Medical Society, by Dr. R. N. Khory, and from first to last it is an excellent *résumé* of, and commentary upon, the many events of medical interest which took place in India during the past year. Among other matters dealt with are the report of the Leprosy Commission, and the alcohol and opium questions, upon which Dr. Khory has much which is instructive to say. This *Review* has made a capital beginning in this, the second year of its existence, and we cordially wish it a successful career.

⁂

Dr. Lockhart Gillespie has been awarded the Freeland Barbour Biennial Fellowship by the Royal College of Physicians, Edinburgh, for his work on "Digestion and Dyspepsia." We may add that the author was for some time engaged in making experimental researches in the laboratory of the Royal College of Physicians of Edinburgh, the results of which were embodied in a paper read before the Medico-Chirurgical Society entitled "Some Practical Results from the Chemical Examination of the Contents of the Healthy Stomach," and which was subsequently published in the *Edinburgh Medical Journal*.

⁂

The author of "Leishman's Midwifery"—the text-book *par excellence* twenty years ago—is no more. Thousands have felt the pleasure of conning their Leishman; (textbooks are not pleasurable reading as a rule) and another thousand or more may be added to the number of pupils, who for the last quarter of a century have had the privilege of his personal instruction as Regius Professor of Midwifery in Glasgow University, where his wonderful faculty of imparting knowledge, drew large and enthusiastic classes. The deceased resigned his chair but a few months since from ill-heath, and now we are called upon to record his death which occurred last week at the age of sixty.

⁂

The January number of Mr. Hutchinson's *Archives of Surgery* (J. & A. Churchill) contains a large amount of interesting matter. They are, in print, what the editor's weekly demonstrations are clinically, a *recueil* of valuable and often rare observations, the salient features of which are rendered more prominent by lithographic and coloured plates. Mr. Hutchinson continues his comparison of the mortality from strangulated hernia treated by herniotomy and taxis respectively, and he fully maintains his well-known predilection for the latter. He has taken an immense amount of trouble to collect statistics of the result of former and present practice in this respect, but many will doubt whether the matter is one that admits of settlement on a purely numerical basis.

⁂

The literature of "doctoring" as it is commonly termed is not calculated to elevate the profession in the public estimation. Some of the touting leaflets sent us almost weekly of so-called "provident dispensaries are almost as degrading as is the practice of medicine at

Bagdad. Here, we are told, by one of our Indian exchanges, patients are constantly bargaining with the physician for a cure, and refuse to pay for advice pure and simple, or for an examination, no matter how much skill or time it may involve, until the cure is completed. Here too are benevolent societies whose secretary receives as salary a certain amount on *every prescription* he has to settle for, and then he and the doctor agree that a new prescription shall be written for every dose!

⁂

New Books and New Editions.—The following have been received for review since the publication of our last monthly list:—Text-book of Diseases of the Ear, by Prof. Politzer, of Vienna, translated by Dr. Dodd, and edited by Sir Wm. Dalby, M.B., F.R.C.S., 3rd edition. Two Great Scotsmen, the brothers Wm. and John Hunter. Index Pathologicus, by James C. Howden, M.D. Clinical Lectures on Recent Surgery, by Arthur T. Norton, F.R.C.S. Nursing in Eye Diseases, by C. S. Jeaffreson, M.D., F.R.C.S. The Year-book of Treatment for 1894. Trephining in the Ancient and Modern Aspect, by J. Fletcher Horne, M.D. Aids to Forensic Medicine and Toxicology, by Wm. Murrell, M.D., F.R.C.P. Kelly's London Medical Directory for 1894. Archives of Surgery, by Jonathan Hutchinson, LL.D., F.R.S., vol. v, No. 19. Half-yearly volume of the Liverpool Medico-Chirurgical Journal. The Physicians Appointment Diary for 1894. Atlas of Clinical Medicine, vol. ii, part 3, by Byrom Bramwell, M.D. Illustrations of Pathological Anatomy, by Professors Kast and Rumpel, English edition by Dr. Armand Ruffer, part vii. Royal London Ophthalmic Reports, vol. xiii, part iv. Sprains, their Consequences and Treatment, by C. W. Mansell-Moullin, M.D. Oxon. Manual of Practical Anatomy, vol. ii, by Hy. D. J. Cunningham, M.D. Ed.

ALLINSON *V.* THE GENERAL MEDICAL COUNCIL.

RESULT OF APPEAL.

The original action (tried before Mr. Justice Collins last June) was for a declaration that the decision of the Defendant Council directing the erasure of the name of plaintiff from the "Medical Register" was invalid and void; for an injunction to restrain the Council from erasing the plaintiff's name or allowing his name to remain erased from the "Register," and from publishing such decision; and for a *mandamus* to compel the Council to restore the plaintiff's name to the "Register." Plaintiff was a Licentiate of the Colleges of Physicians and Surgeons of Edinburgh, in practice, and registered under the 1858 Act, by sec. 29 of which the Council have the power to erase from the "Register" the name of any registered practitioner who shall, after due inquiry, be adjudged guilty of infamous conduct in a professional respect. The plaintiff (on the complaint of the Medical Defence Union) received a notice on May 14th, 1892, to appear before the General Medical Council and to answer to a charge of having been guilty of such conduct, the particulars of which being that the plaintiff had systematically sought to attract practice by a system of advertisements. Dr. Philipson was a subscribing member, a vice-president and guarantor of the Defence Union; and, as vice-president, was also an *ex-officio* member of the Executive Committee. Dr. Philipson became a member of the General Medical Council on May 3rd, 1892, on which day he resigned his membership of the Union. It appears that by the rules of the Union a resignation does not take effect for two months after its receipt. Dr. Philipson had never taken any part in the proceedings of the Executive Committee of the Union, and had had no share in making the complaint against the plaintiff. This complaint was supported before the Council by the secretary of the Union. Dr. Philipson attended the meeting of the Council on May 28th, 1892, when the plaintiff's name was directed to be erased from the "Register" on the above-mentioned ground. Mr. Justice Collins gave judgment for the Defendant Council, and against this judgment the plaintiff appealed last Friday (Feb. 23rd, 1894), before Lord Esher (the Master of the Rolls) and Lords Justices Lopes and Davey. Mr. Bernard Coleridge, Q.C., appeared for the appellant, and Mr. R. T. Reid, Q.C., for the respondent Council.

Mr. Coleridge, in the course of his argument, said that an inquiry by the General Medical Council was a judicial inquiry, and therefore all the rules applicable to a judicial inquiry applied to this inquiry. Although he admitted that Dr. Philipson had stated in his affidavit that he did not know the nature of the charge, or the name of the party charged, he contended that every person who was an active member of the Union was also an accuser, and therefore a partisan, and it was not requisite that there should be any unworthy bias at all. In reply to the Master of the Rolls, he said that the accusers in fact were those members of the Committee of the Union who had got up the case, but that those members of the Committed were the agents of Dr. Philipson, who, although he had not himself taken any active steps in the prosecution, had been, through his agents, an accuser, and he subsequently sat as a judge. He further contended that, if even an absent member of the Council had been one of the prosecuting body, that fact would have been sufficient to invalidate the action of the Council. Allinson had written a pamphlet, "How to Avoid Vaccination?" [Lord Justice Lopes: In which he had advised people to break the law.] He had advised parents not to allow more than one "mark" to be made, and to wipe the child's arm immediately after the operation. In 1888 Allinson had made a promise to the College of Physicians of Edinburgh that he would withdraw the pamphlet from circulation, and this promise he had kept, but before he had made it, some Anti-Vaccination Society had got hold of it and published it. It could not be said that simply because his opinions did not quite agree with those of other medical men he should be punished.

[The Master of the Rolls: His absurd opinion might not be of much moment, but he had put them into practice upon patients.]

Mr. Coleridge maintained that a medical man could not be said to be guilty of "infamous conduct" on account of his being opposed to the eating of flesh-meat, to vaccination, and to the use of tobacco. The conduct impugned must be "infamous" *per se*, and not merely what might be objectionable only in a member of a given profession *quâ* his strictly professional conduct.

Mr. Reid, on the other side, pointed to the fact that Allinson had, in the *Echo* newspaper, advised people to go to druggists' shops for application of strong nitric acid to moles, although he had previously expressed his disapproval of caustics, and of medicines in general, which he had referred to as "doctors' poison;" after his promise to the College of Physicians of Edinburgh he had directed persons to obtain the pamphlet from the Anti-Vaccination Society, and had professed to give advice by correspondence with the unseen amateur diagnosers of "kidney disease" without requiring the opportunity for examining the urine.

The Master of the Rolls, in giving judgment, dealt with the first point which had been raised, which was that Dr. Philipson was in such a position that he might be biassed, and that he had been an accuser as well as a judge. Referring to the decision in the case of "Leeson against the General Medical Council" (heard in that same court), he said that there the question of pecuniary interest and of bias had been considered, and, in regard to bias, where the relation of the party concerned was such that by no probability could there be any bias, no objection could be taken. It was not for that Court to inquire whether a person was or was not biassed. There must be some position between these two extremes. The person must be in such a relation to the matter that he could not *reasonably* be suspected of bias. The question, therefore, was, "Could Dr. Philipson reasonably be suspected of bias?" Considering all the facts in regard to Dr. Philipson, the Medical Defence Union and the Medical Council which had appeared in evidence in the Court below, and looking at the substance rather than to the technicality, Dr. Philipson had, so far as in him lay, resigned his membership. Under these circumstances he could not *reasonably* be suspected of bias, and this contention therefore failed. The second point raised was that there was no evidence that the plaintiff was guilty of "infamous conduct in a professional respect." As to this he (the Master of the Rolls) would adopt a definition of Lord Justice Lopes' as being applicable to this case, and it was to this effect: if a medical man in pursuit of his profession had done something with respect to it which would reasonably be regarded as infamous by his professional brethren of repute, his so doing would be evidence of infamous conduct in a professional respect. Whether what a medical man (in any particular case) may have done would be infamous if done by some one who was not a medical man was not the question to be considered, since the conduct must be "infamous in a professional respect," and the definition which he had adopted would show the circumstances in which the respondent Council would be justified in finding a medical man guilty of infamous conduct in a professional respect. Did the evidence that was before the Council, when taken as a whole, bring the plaintiff within that definition? In his opinion there was evidence upon which the Council could say that the plaintiff had tried to defame his brother practitioners, and had tried to induce suffering people to refrain from going to them and to come to him instead, and, in this way, to enable him to receive fees which otherwise would have gone to them. Therefore there was evidene upon which the Council were justified in finding the appellant guilty of infamous conduct in a professional respect. His judgment was that the decision of the Council was final, and could not be reviewed, and with this judgment the two Lords Justices concurred.

◆

Medical News.

International Medical Congress, Rome.

The Secretary-General of the International Medical Congress to be held in Rome on the 29th prox., has forwarded documents for identification to all who have enrolled themselves as members. Those members of the Profession in Ireland who possibly may not as yet have received them, as well as those who purpose becoming members, should apply for cards of membership, instructions, programmes, &c., for themselves and for their relatives who may desire to accompany them to Rome, to Sir William Stokes, Chairman of the Irish National Committee, 5 Merrion Square, Dublin, and, after March 5th, to Sir Philip C. Smyly, 4 Merrion Square.

The British Medical Association.

The arrangements for the Annual Meeting of the Association are now nearly complete. Bristol being the town selected, Dr. E. Long Fox, of Clifton, has been nominated President-Elect, Dr. Fyffe, Local Hon. Treasurer, and Dr. Markham Skerritt, Local Organising Secretary. The date of the Congress has been definitely fixed for Tuesday, Wednesday, Thursday, and Friday, July 31st, and August 1st, 2nd, and 3rd. The reception room will be at the Victoria Rooms, where also the addresses to the general body of members are to be delivered and the annual banquet will take place. Of the nine sections, eight will meet in the buildings of University College, in the departments allotted to the faculty of arts and sciences and to the faculty of medicine. The sections, with their respective presidents, are:—Medicine, F. T. Roberts, M.D., of London; Surgery, W. Mitchell-Banks, M.D., of Liverpool; Obstetric Medicine and Gynæcology, J. G. Swayne, M.D., of Clifton; Public Health, W. H. Corfield, M.D., of London; Psychology, G. M. Blandford, M.D., of London; Pathology, G. Sims Woodhead, M.D., of London; Ophthalmology, F. Richardson Cross, M.B., of Clifton; Laryngology and Otology, P. McBride, M.D., of Edinburgh; Dermatology, A. J. Harrison, M.B., of Clifton; Children's Diseases, W. H. Dickinson, M.D., of London. The meetings of the Public Health section are to be held in the theatre of the Museum and Library, this being the only section to which persons who are not members of the medical profession are admitted. The principal addresses delivered will be on "Medicine," by Dr. T. Grainger Stewart, of Edinburgh; "Surgery," by Dr. J. Greig Smith, of Clifton; and Sir Charles Cameron, M.D., of Dublin, will deal with a subject relating to public health.

Opening of the New Dental Hospital.

On Saturday, H.R.H. the Duke of York formally opened the new National Dental Hospital and College in Great Portland Street, London. The building, which is the gift of the Dowager Lady Howard de Walden, has cost some £10,000 to erect. It is a handsome structure, with an exterior of red brick, and comprises a large lecture hall, laboratories, special demonstration rooms, a stopping room capable of accommodating 75 patients, and other offices.

Laryngological Society of London.

At the last meeting of the Laryngological Society of London, the following gentlemen were elected honorary members of the Society, in recognition of the distinguished service they have rendered to the cause of laryngology'—Sir George Johnson, M.D., F.R.S.; Professor B. Fraenkel, Berlin; Professor von Schroetter, Vienna; Dr. Wilhelm Meyer, Copenhagen; Dr. J. Solis-Cohen, Philadelphia; Dr. G. M. Sefferts, New York; Professor Massei, Naples; Dr. E. J. Moure, Bordeaux.

Royal College of Surgeons in Ireland—Fellowship Examinations.

The following gentleman, having passed the necessary examinations, has been admitted a Fellow of the College:—

Mr. William John Russell, West Maitland, New South Wales, L.R.C.P.I., and L.R.C.S.I.

The following gentlemen have passed the Primary part of the examinations for the Fellowship of the College:—

Mr. Patrick Thomas Bolger, Christ Church, New Zealand, L.R.C.P.I., and L.R.C.S.I., and Mr. Jeremiah Dowling, Tipperary, L.R.C.P.I. and L.R.C.S.I.

Royal University of Ireland.

At a meeting of the Senate the following were appointed Medical Fellows of the University:—

Anatomy—A. E. J. Birmingham, M.D., Joseph P. Pye, M.D., J. Symington, M.D. Physiology—John J. Charles, M.D., Charles P. Coppinger, M.D. Medicine—John Isaac Lynham, M.D. Surgery—Patrick J. Hayes, M.D., M.Ch., Wm. Thornley Stoker, M.D.

The following were appointed Examiners of the University for 1894:—

In Natural Philosophy—Alex. Anderson, M.A., John England, M.A. In Mental Science—W. A. FitzHenry, M.A., LL.B. In Biology—Rev. L. M. Reynard Klein, D.Sc., A. J. M. Blaney, M.B. In Medicine—J. P. O'Carroll, M.D. In Midwifery—J. W. Byers, M.D., A. J. Smith, M.B. In Materia Medica—F. J. B. Quinlan, M.D., William Whitla, M.D. In Ophthalmology—L. Werner, M.B., J. Walton Browne. In Medical Jurisprudence—C. Y. Pearson, M.D., A. Roche, M.D. In Pathology—W. H. Barrett, M.B., E. J. M'Weeney, M.D. In Sanitary Science—Sir Charles Cameron, F.R.C.S.I.

Indian Medical Service.

The Military Secretary, India Office, sends us the following as the official list of the candidates for Her Majesty's Indian Medical Service who were successful at the Competitive Examination, held at Burlington House on the 9th to 17th February, 1894. Forty-three candidates competed for fourteen appointments. Twenty-six were reported qualified. The names are arranged in order of merit:—

	Marks.		Marks.
G. Ramsay	81[illegible]0	H. M. Moore	2442
D. W. Sutherland	2754	A. W. F. Russell	2381
W. Selby	2606	D. C. Johnston	2304
H. J. K. Bamfield	2604	C. R. Pearce	2304
W. D. Hayward	2565	J. W. Grant	2291
A. H. Moorhead	2475	W. B. Bennett	22[illegible]6
T. A. Granger	2470	W. E. Scott Moncrieff	2192

Army Medical Service.

The following is an official list of successful candidates for Commissions in the Medical Staff of Her Majesty's Army at the recent examination in London, arranged in order of merit:—

	Marks.		Marks.
Evans, P.	2849	Milner, A. E.	23[illegible]0
Silver, J. P.	2462	Sweetman, S. W.	236[illegible]
Buist, J. M.	2391	Dove, F.	2345
Vaughan Williams, H. W.	2390	Morgan, C. K.	2[illegible]82
Walker, J.	2365	Thom, G. H. C.	2178

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 34, Bombay 31, Madras 48, Paris 22, Brussels 17, Amsterdam 20, Rotterdam 26, The Hague 17, Copenhagen 22, Stockholm 17, Christiania 14, St. Petersburg 31, Moscow 29, Berlin 18, Hamburg 17, Dresden 21, Breslau 26, Munich 27, Vienna 26, Prague 29, Buda-Pesth 26, Trieste 34, Rome 25, urin 35, Venice 37, Cairo 56, Alexandria 59, New York 22, rooklyn 18, Philadelphia 25, New Orleans 27.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

DR. HUXLEY (Maidstone).—Your letter is unavoidably held over.

DR. ILLINGWORTH.—1. Regret we have not space for grievances against contemporaries. 2. The investigations will appear in the same form as before as soon as space permits.

MR. S. WILTON.—Measured by their relative populations, Berlin is larger than Vienna by about 250,000, but the latter occupies a slightly larger area. Neither city would be taken as a model in sanitation, the death-rate from preventible diseases being in both cases higher all the year round than London, which is three times greater in extent than either.

DR. MYRTLE'S paper on "The Spread of Chronic Skin Diseases by Heat" is marked for early insertion. Proof shall be sent in due course.

REMARKABLE ESCAPE.

OUR Glasgow Correspondent writes: When the North British train from Glasgow to Helensburgh reached Charing Cross (Glasgow), on Friday night, a drunken man stepped out, and on the train restarting he fell over the buffers between the carriages, nearly all the train passing over him. The porters found him on his back uninjured and complacently smoking. When asked if he was hurt, he replied, "Not a bit, I have been in the Crimea."

MR. F. E. PIRKIS.—We are not implicit believers in the system. On the other hand, we do not see the matter in the same light as the news you send us for insertion would seem to convey.

Meetings of Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 28TH.

HUNTERIAN SOCIETY.—At 8.30 p.m., Dr. Pye-Smith: Rational Therapeutics.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. Chas. Stewart: The Physiological Series of Comparative Anatomy in the Museum of the College.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. J. Kingston Fowler: Cases of Pulmonary Tuberculosis. Royal London Ophthalmic Hospital, Moorfields.—At 8 p.m., Mr. A. S. Morton: Optic Neuritis. Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Alopecia, its Varieties.

WEST LONDON HOSPITAL (Hammersmith).—At 5 p.m., Mr. Stephen Paget: Diseases of the Breast. (Post-Graduate Course.)

THURSDAY, MARCH 1ST.

HARVEIAN SOCIETY.—At 8.30 p.m., Dr. J. F. W. Silk: On the Use and Abuse of Anæsthetics.

LONDON POST-GRADUATE COURSE.—National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Gowers: Clinical Cases. Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Mr. Jonathan Hutchinson: Cases in the Wards.

FRIDAY, MARCH 2ND.

CANCER HOSPITAL (Fulham Road, S.W.).—At 4 p.m, Dr. Snow: Non-malignant Tumours of the Breast.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. J. Kingston Fowler: Cases of Valvular Disease.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Medical Section, in College of Physicians, at 8 p.m., Dr. J. Little: The Sequel of a case of Myxœdema treated by Thyroid Juice.—Dr. M. F. Cox: On the Treatment of Bright's Disease.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. Chas. Stewart: The Physiological Series of Comparative Anatomy in the Museum of the College.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Miller Hospital, Greenwich).—At 8 p.m., Sir Dyce Duckworth: Some Points in the Diagnosis of Pain commonly called Gouty or Rheumatic.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital).—At 8 p.m., Special general meeting to consider certain alterations in and additions to the laws. At 8.30 p.m., Clinical Meeting:—Drs. Gardner, Dockrell, and Masters: Cases of Psoriasis treated by Thyroid Extract.—Dr. Abraham: Other cases of Skin Diseases.—Dr. Gardner and Mr. Steer: Cases of Myxœdema.—Dr. Chapman: Case of Valvular Disease of Heart in a Child; case of Progressive Muscular Atrophy; case of Senile Phthisis.—Dr. Neville Wood: Case of Hæmophilia.—Dr. Morgan Dockrell: One of the Ulerythemata.

SATURDAY, MARCH 3RD.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital, at 11 a.m, Dr. Hyslop: General Paralysis of the Insane.

MONDAY, MARCH 5TH.

ODONTOLOGICAL SOCIETY.—At 8 p.m., Mr. T. E. Constant: Pental. Casual Communications will be given by Mr. E. W. Roughton and Mr. W. R. Humby.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Eczema.

MONDAY, MARCH 12TH.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. Chas. Stewart: The Physiological Series of Comparative Anatomy in the Museum of the College.

Vacancies.

Carmarthen Joint Counties' Lunatic Asylum.—Medical Superintendent. Salary £500 per annum, with unfurnished house, washing, &c. Applications and testimonials to the Clerk to the Visitors by 24th March.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c. Applications and testimonials to the Secretary, 24 Finsbury Circus, E.C., by 3rd March.

County Asylum, Prestwich, Manchester.—Assistant Medical Officer (unmarried). Salary £100 per annum, increasing to £200, with apartments, board, attendance, and washing. Applications to the Superintendent.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer (unmarried). Salary £100 per annum, with annual rise of £25 up to £200, with apartments, board, and washing. Immediate application to the Medical Superintendent.

County of Northumberland.—Medical Officer of Health. Salary £500 per annum and travelling expenses. Applications and testimonials to the Deputy Clerk of the Council by 24th March.

Croydon—The Borough Isolation Hospital for Infectious Diseases.—Resident Medical Officer. Salary £120 per annum, with board and lodging, increasing by £20 at the end of the first year. Applications and testimonials to the Medical Officer of Health, 7 Katharine St., Croydon, by March 1st.

Manchester Royal Infirmary—Monsall Fever Hospital.—Assistant Medical Officer (unmarried). Salary £100 per annum, with board and residence. Applications and testimonials to the Chairman of the Board by 3rd March.

Manchester Royal Infirmary.—Resident Medical Officer of the Convalescent Hospital at Cheadle (unmarried). Salary £150 per annum, with board and residence. Applications and testimonials to the Chairman of the Board by 3rd March.

Royal South Hants Infirmary, Southampton.—House Surgeon. Salary £100 per annum, with board and lodging. Applications and testimonials to the Secretary by March 10th.

Sir Patrick Dun's Hospital, Dublin.—Assistant Physician on the Staff in charge of Out-patients. Applications before March 8th. (See advert.)

Appointments

BANKS, WM., M.B.Lond., M.R.C.S., an Hon. Medical Officer to the New Hospital, Falmouth.

BULLMORE, W. K., M.D. St. And., M.R.C.S., an Hon. Medical Officer to the New Hospital, Falmouth.

HARRIS, A. B., M.D. St. And., M.R.C.S., Hon. Medical Officer to the New Hospital, Falmouth.

HICKEY, Dr. G., Medical Superintendent for the Borough of New Ross.

LANYON, G. E., M.B., C.M.Ed., an Hon. Medical Officer to the New Hospital, Falmouth.

MAXWELL, R., M.B., C.M.Ed., House Physician to the Northern Hospital, Liverpool.

MOORE, E. H., L.R.C.S.Ed., an Hon. Medical Officer to the New Hospital, Falmouth.

MUSSEN, A. A., M.B., B.Ch.Dub., Assistant House Surgeon to the Northern Hospital, Liverpool.

PERCEVAL, F., L.R.C.P.Lond., M.R.C.S., Medical Superintendent of the County Asylum, Whittingham, Lancs.

WALSH, M., L.R.C.P., L.R.C.S.Irel., Medical Officer to the Royal Irish Constabulary for Wexford and Kilkenny.

Marriages.

CARRELL—HADDOW.—Feb. 24th, at the Wesleyan Chapel, East Dulwich, Geo. N. P. Carrell, M.R.C.S.; L.R.C.P., of Ilford, to Sage Ward, daughter of Nathaniel Haddow, of Dulwich.

Deaths.

BOULTON.—Feb. 24th, at 6 Seymour St., London, W., the beloved wife of Percy Boulton, M.D., aged 51.

CLARKE.—Feb. 16th, at Banbury, Thomas Clarke, M.R.C.S., aged 72.

CRAIGIE.—Feb. 19th, at Bournemouth, James Craigie, M.D., of Hoylake, Cheshire.

LEISHMAN.—Feb. 18th, at Blairmore, William Leishman, M.D., Emeritus Professor of Midwifery in the University of Glasgow.

LUKE.—Feb. 19th, at his residence, Hayes, Slinfold, Sussex, Henry Luke, M.R.C.S.

GABB.—Feb. 24th, at St. Arvans, Abergavenny, Alfred Wm. Gabb, M.R.C.S., L.S.A., aged 74.

GRAHAM.—Feb. 17th, at West Kensington, Sydney D. Graham, M.R.C.S., M.R.C.P., only son of Major-General J. M. Graham.

NEWTON.—Feb. 16th, at 85 Gloucester Terrace, Hyde Park, Edward Newton, F.R.C.S., aged 78.

REYNOLDS.—Feb. 13th, at his residence, 165 Rathgar Road, Francis E. Reynolds, Deputy-Inspector-General of Hospitals, aged 74.

ROSSITER.—Feb. 17th, at his residence, Priory Place, New Ross, Thomas Rossiter, M.D., aged 83

SMITH.—Feb 15th, at Point de Galle, Ceylon, H. L. Barton Smith, M.D., M.R.C.S., of 29 Charles Street, London, W., aged 45.

WILLIS.—Feb. 14th, at Florence Court, county Fermanagh, William Willis, M.D.Edin., F.R.C.S.Eng., Physician to Her Majesty's Legation, Bangkok, Siam, aged 57.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

Berlin Clinical Lectures.

RECENT INVESTIGATIONS ON THE PATHOLOGICAL ANATOMY OF TABES.

By. PROF. LEYDEN, M.D.,
University of Berlin.

[SPECIALLY REPORTED BY OUR OWN CORRESPONDENT.]

PROF. LEYDEN said it was thirty years since his first works on this subject had been published, and this accidental circumstance formed one of the reasons why he again expressed himself in a comprehensive manner on the subject. He had then tabulated three forms of the grey degeneration of tabes :—

1. The grey degeneration of tabes.
2. The grey degeneration of multiple sclerosis.
3. That of secondary degeneration.

The main pathologico-anatomical works were based on the previous investigations of Cruveilhier, and others; these were the first methodical and properly arranged investigations. In his monograph on tabes of 1863 his aim was to delineate the pathological anatomy of the disease with the utmost possible accuracy, and to bring the clinical disease into unison with it, that it could be understood from the changes, and thereby gain a basis for a more certain diagnosis. The aim was in fact achieved. Previous labours of several authors did not show a methodical system. The views announced in the work, related (1) to the pathological anatomy, and (2) the pathological physiology.

As regarded the pathological anatomy the result was that the process was not properly inflammatory, but a peculiar degeneration, a process that had affected the nerve elements of the fibres implicated. This was something new, and in contradiction to the ruling view, for up to then a chronic myelitis only had been spoken of. The French school quickly took up the view of a parenchymatous process.

Of greater importance, however, was the view on the extension of the process. The peculiar degeneration of the nerve elements was continued to the region of the sensory portion of the spinal cord, and progressed upwards over the sensory portion of the cord. The simultaneous degeneration of the posterior roots was also emphasised. The principal part of the pathological physiological explanation was that the disease was one of the sensory nerves, starting in the roots that corresponded to the primary sensory tracts.

The results were received at first with great favour; but this did not last long, diverging opinions soon appeared from Cyon, Niemeyer, and Späth, but the case of the latter was one that is now recognised as being one of syringomyelia. Other works by the author then followed, but they did not succeed in obtaining general recognition. At the same time two other works were published that attracted a good deal of attention, the one was by Eisenmann on ataxia, based on Duchenne's description; but nothing could be made of it. He had collected the material with great care, but was not able to properly arrange it. Then Friedreich published a work on atrophy of the posterior columns of the cord, but his cases were mixed, so that a decided analysis could not be arrived at, either from the pathologico-anatomical side or the clinical. From this we have "Friedreich's" disease.

Then came another current from the setting up of the theory of diseases of systems, here were two works to be specially mentioned, the one by Flechsig, the other by Pierret, both running in this direction. The first view arose from embryological studies. It was found that in the embryo the spinal column was not traversed by nerve fibres with regularity, but in certain phases, according to which systems could be erected. These systems were based in part on investigations by Türck. The more accurate carrying of them out was on this basis in French investigations. Almost simultaneously appeared the work of Pierret, prepared under the auspices of Charcot; this author had attempted to determine the commencement of the pathological anatomical changes in tabes. In one case he found that it was in certain regions of the posterior columns, in immediate proximity to the radiations of the roots, that the disease commenced. This fact was adopted by Charcot, and then generally accepted. These regions were looked upon as spots of predilection in commencing tabes, and at the same time designated as the seat of co-ordination. In atrophy of them incoordination was said to take place. No proof of this had, however, been brought forward. It was further accepted that the posterior roots passed through these spots, and that anæsthesia and pain were thereby explained.

The doctrine of disease of systems had developed from the observation of Vulpian. Since then the view had more and more extended in Germany that tabes originated in certain parts of the cord, and that it was a systemic disease. Flechsig had not spoken out clearly on the anatomy of tabes; he had only said that it began in the parts lying between Burdach's and Goll's columns. Then arose the view that the posterior columns did not constitute one system, but several systems, and that tabes was a combined systemic disease, there were to be added the peripheral parts of the lateral fibres of the cerebellum, a small zone but not unfrequently implicated in tabes, and so the subject was rendered still more obscure.

And now, again, a turn in the position of affairs had taken place, which appeared to support the views advanced by the speaker thirty years ago. As regarded the newer works, which unfortunately had attracted but little notice, the first to be named was that by Emil Redlich "The Posterior Roots of the Spinal Cord and the Pathological Anatomy of Tabes." He came to the conclusion that the posterior columns had no proper fibres, but were solely composed of the fibres of the posterior roots, and that this was the reason why the anatomical process in tabes had its starting point in the posterior roots. In this way the author was distinctly opposed to the view of systemic disease. He stood upon the standpoint of Leyden, who was the first to emphasise the importance of the posterior roots for tabes. In the commencement of the present year Leyden's participation in this had been confirmed by two neurologists in Paris, Pierre

Marie and Déjérine. The first in his work on diseases of the spinal cord had given a very comprehensive and thorough chapter on tabes that contained all the pathological material, at least, the physiological and clinical. He said it was unjustifiable according to the present standpoint to attribute so much independence to the posterior columns that they could become diseased primarily; they became diseased only when cut off from the trophic centre, and these were to be sought in the spinal ganglia. There were also peripheral ganglia, to which he attributed degeneration of the peripheral nerves. After the appearance of this book, M. Déjérine gave an address on the pathological anatomy of tabes. He came to the conclusion that the degeneration of the posterior column in tabes was a secondary one, corresponding to the disease of the posterior roots. The speaker (Prof. Leyden) ascribed the first discovery of this fact to Vulpian, and thought this new revolutionary idea would at first meet with opposition but he was pleased to be able to confirm that it had already been accepted by both German and French authors, or as it appeared they had both arrived at the idea independently of each other, whereupon M. Marie had replied that it was Leyden who first pointed out the importance of the posterior roots. This view had first been given expression to in 1863, and had never been withdrawn, on the contrary, it had in 1888 been again expressed more precisely in connection with his anatomical and physiological works. From this it was concluded that the posterior columns were formed of fibres springing from the posterior roots, or were commissural fibres, and if it could not be proved that they possessed no other fibres, there were no facts to show that other fibres passed into them. Tabes, therefore, developed from the periphery for which proofs should be forthcoming.

GYNÆCOLOGICAL PROGRESS. (a)

By THOMAS SAVAGE, M.D., M.R.C.P., F.R.C.S.,
President of the British Gynæcological Society; Professor of Gynæcology in Masons College, Birmingham; Surgeon to the Birmingham Midland Hospital for Women.

During the past year the good work and advance of knowledge in the particular direction of carcinoma of the uterus, and its treatment by operation, are matters for congratulation, especially to those who have assiduously worked thereat. The effect of this is that the operation has been established on a firm basis as a justifiable one, that very great relief may be obtained by it in suitable cases, and that the early recognition of suitable cases is likely to be more frequent. But time is required to bring about all that we want even in this particular operation. We want to know more exactly the cases best suited for operation, the average addition to life which the operation gives, and especially something more of the details which are known to be most conducive to a successful result in operating. Time will, however, bring about these desiderata, aided by careful observation. No two surgeons would perform the same operation exactly in the same manner. Above and beyond some inconsequent details some operators would, in a given case, apply more, and some would apply less, of the best details: and what is wanted is that the best of all should be made use of by all. The importance of this principle will be more and more manifest when it is universally admitted, as it is beginning to be, that when death occurs after such operations as abdominal section, it is due much more frequently to causes connected with the details of the operation, and therefore personal to the operator, than to any other cause. Hence, as long as any deaths occur after operations which may be attributed to the operation, we shall be far off from finality in our art. And because the personal element possesses such an enormous influence in success or failure—for good or for ill—we must ever be striving to attain to that high ideal—no deaths at all.

Probably during the coming year ventro-fixation of the uterus for prolapsus and some kinds of retro-displacement will engage our attention, and here a few months will be sufficient to elucidate what are the best methods of performing the operation, its safety in regard to mortality due to the operation directly, and its benefits in regard to effecting relief or a permanent cure of the condition for which it was undertaken; also the contra-indications such as the presence of too extensive or firm adhesions, the presence of inflammatory products connected with the appendages, &c. I say a few months will tell us all this; for, with the improved methods of operating, the mortality ought to be very slight indeed in simple uncomplicated cases. It is to be expected that only where extensive adhesions have to be undone, as in some cases of retroflexion, the element of danger presents itself; and here we ought to be able to overcome such by careful drainage. I think that the general consensus of experience of shortening the round ligaments has been that it has been tried and found wanting.

On the Continent complete extirpation of the uterus by the vaginal method has been proposed and practised for complete prolapse: and it has seemed to me, so far, that in a few cases of complete prolapse in women who have passed the menopause, and are therefore incapable of future conception, to whom their condition makes their life a burden, this operation may be offered as an alternative. Seeing that the uterus is completely outside, and in full view, the operation is a simple one to perform, and should not be associated with more risk than ventro-fixation.

By many gynæcologists both these operations may at first be considered heroic in the extreme—perhaps too heroic—and it must be borne in mind in judging of the advisability of recommending, and the justifiability of performing them, that they are operations of expediency rather than of necessity, and are undertaken for conditions which do not threaten life. Therefore the risks and objects of each should be plainly laid before the patient, and it should be for her to elect or refuse to submit to undergo them. At the same time we often find that the discomfort is so unbearable, and the inability to enjoy the pleasures and perform the duties of life is so great, that it is justifiable to incur some amount of risk for the prospective advantages of a successful issue; and many suffering women are quite willing to incur this. In the Paris Academy of Sciences last December Dr. Lejars related two successful cases, up to which time there had probably been thirty or forty operations for this extreme condition. An objection has been raised that the operation has been followed, within a short time of its performance, by a slight prolapse of the vaginal wall. To obviate this certain operators insist on the necessity for excising a large piece of the vaginal wall, while others recommend the vagina to be fixed in position by stitching to the peritoneum above. Dr. Lejars prefers the removal of two large triangular flaps from the lateral walls of the vagina, followed by double colporrhaphy.

I have had some experience of the operation of extirpation for prolapse, and can testify to its facility and safety.

Of course the consideration of the subject of hysterectomy for myoma is not yet complete; not is it likely to be for some long time to come. It has become chronic. Myoma of the uterus is a hydra-headed monster, which needs all the resources of our art, all our judgment, and more than all our present dexterity to enable us to combat it successfully. The multitudinous and various suggestions and modifications of details for its performance are all good, more or less, and advance us by slow steps to that goal which we are all so anxious to reach With our present lights, the risks are often so enormous that I am inclined to think it is not now so frequently performed as was the case a few years ago; certainly that is my own position and experience. Many men, I believe, decline to undertake it except in those desperate cases where the patient would manifestly die without it. Assuredly, one reason for its less frequent performance is the alternative which we possess in removal of the appendages, which operation is attended with such brilliant results, when it can be satisfactorily and completely performed, and is done early enough. And yet what a surgical triumph is hysterectomy when successful! There is in the whole range of surgery nothing to excel it, few operations to equal it! Every successful operation makes the performer of it proud of his art, and feel that there is still something to live for. The pity of it is that much too frequently the patient does not take the opportunity of having the surgical aspects of her case considered until so late in the progress of her malady. There is a too deeply ingrained idea in the medical mind that fibroids of the uterus are of little importance either to health or life, and that all will come right at the menopause. Of the recent suggestions for perfecting the operation, the majority have in view the shutting off of the peritoneum from infection —below, through the uterine canal; and above, through the stump. In attempting the latter, where it is practicable, Dr. J. W. Taylor's method of passing the transfixion pins through the parietal peritoneum on each side may be tried with advantage. Though a modification in detail, I believe it is similar in principle to what was suggested by Dr. Bantock many years ago, and has been practised with success by myself and others—viz., making the suture above and the suture below the stump to include a portion of the stump on the proximal side of the clamp.

(a) Abstract of Presidential Address delivered before the British Gynæcological Society, February, 1894.

During the past year, especially in London, much attention has been given to the interesting and very important subject of inflammation and suppuration in the pelvis; and advance is being gradually made towards a more perfect knowledge of its causes and pathology. Our interest becomes more and more centred in the uterine appendages, and perhaps less so in the connective tissue of the broad ligaments; and we find that we are getting to have a much better knowledge of cases which are appropriate for operation.

But, while we look with satisfaction upon the frequent cure, by operation, of cases which otherwise would be incurable, one cannot but feel at times that ablation of a diseased organ is not the ideal scientific method of curing it; and one is constrained to ask oneself, therefore, if we shall ever be able to find an alternative method? At present, with the lights of to-day, that time seems certainly a long way off.

"*Obsta principiis.*" Doubtless, prevention of those causes which are frequently at the bottom of such cases will be the first step in their diminution; and this may be looked for speedily, when the practice of aseptic and antiseptic midwifery becomes universal: as it ought, when brought about, to cut off all those cases which arise from direct infection of the parturient canal.

There is one object which our society has very much at heart, and that is that general practitioners should be encouraged to take an active interest in its work. It is quite certain that in their busy and arduous lives they must meet, from time to time, with many interesting cases which it would be both instructive and profitable to us all to discuss in this place; and we should welcome them equally with, if not more than, many of the brilliant triumphs of modern surgery. The observations of men who have seen rare cases, and the riper experience of "all-round" men would be most valuable. Dazzled, perhaps by the more striking results obtained by surgery, there may be a fear that therapeutics and the medical aspects of gynæcology may not receive the amount of attention which they undoubtedly deserve; and here, at all events, is a fertile field in which the general practitioner may usefully direct his energies.

One great difficulty which the surgeon has to contend with is to keep in touch with his cases for any length of time after operation. He is aware, of course, of the immediate results of his operations; and perhaps in publishing these he is apt to make too much of them, valuable though they are both for comparison and emulation; but too often the ultimate results are imperfectly known to him in consequence of the removal of the patient to a distant or unknown address. Would it be possible or practicable for general practitioners to make it a rule, when they meet with these cases in their daily rounds, to tabulate them, ascertain all details as to cure or relief obtained, and then to publish them, discuss them in our society, or communicate them to the respective operators? I cannot but think that such work would be of the most valuable kind; and it would aid us in arriving at conclusions very much more quickly than otherwise, without such assistance, we should be able to do.

Special points which, among others, it would be useful to inquire into and report upon would include the state of general health of the patient; the more or less complete realisation of the object for which the operation was undertaken; the presence or absence of hernial protrusion at the site of the scar, at either its upper or lower end, when a drainage tube, had been used; with any other particulars connected with it that might be worth knowing. Only these few points are noticed here. A careful examination of the patient by a careful observer would readily aid others, if and when they were present; and fresh observations for inquiry into would soon suggest themselves to men of an inquisitive turn. General practice necessarily entails a life of more or less routine, considerable monotony and much fatigue, and I cannot but think that if some of our hardworked brethren would take up some slight additional work upon the lines that I have briefly and imperfectly referred to, it would be greatly to their own advantage as well as ours, and it would certainly add a zest and interest to that large portion of their work which is so much taken up with apparently unimportant details.

In regard to one point just referred to—ventral protrusion after abdominal section—I question if there is any operator who can say, with any approach to accuracy, what is the frequency with which it occurs, or what are the most important factors in its production; whether and how far it is brought about by the length of the incision, the thickness and fat of the abdominal wall, the use of the drainage tube, the closeness or the method of application of the sutures, &c.

For my own part I have always been inclined to a frequent use of draining, and my reason for this is that I have desired to err, if at all, on the safe side. I cannot recall any harm arising directly from its use; nor have I thought, so far, that ventral hernia, at the site of the tube, has been more frequent than in cases in which it has not been used.

We, as representing the new departure, have two principal duties before us, which we shall do well to keep in view of this society. The first duty is to make the utmost progress by observation and practice; and the second is to communicate the results of our knowledge to others. The fulfilment of these two objects this society has at heart during the coming year in advancing those *artes quæ prosunt omnibus.*

◆

RECENT DEVELOPMENTS IN STATE MEDICINE. (a)

By E. EDGAR FLINN, D.P.H., F.R.C.S., M.R.C.P.,

President State Medicine Section of the Royal Academy of Medicine in Ireland; Examiner in State Medicine, Royal Colleges of Physicians and Surgeons' Conjoint Board, &c.

AT the meeting of the Sanitary Congress held at Dublin in 1884, now just ten years ago, I communicated a paper on the administration of the Public Health Act in Ireland. which elicited a discussion, not without interest, in which Sir Robert Rawlinson, C.B. (the President); the much regretted Dr. Alfred Carpenter, of Croydon; Professor De Chaumont, F.R.S., of Netley; Sir Charles Cameron, and others, took part. Since that time considerable developments have taken place, and the administering of the Public Health Acts has undergone an improvement for the better. The Legislature has aided in this direction, and the passing into law of such useful measures as the Housing of the Working Classes Act, the Infectious Diseases Notification Act, the Open Spaces Act, the Contagious Diseases Act, the Factory and Workshops Act, the Margarine Act, have all had a useful and far-reaching influence.

The improvements consequent on this legislation, though slow in making itself felt, will eventually have a good effect; and though our Irish public bodies yet lack energy in moving forward on the questions immediately affecting the health of the people, there is, however, a visible improvement on the conditions that existed some years ago, and there is some inclination shown to carry out the State enactments relating to health. The cry of not burdening the overtaxed ratepayer is, however, yet heard; but the creation of an intelligent public opinion grows more and more every year, and the nationalisation of the questions of Health Economy now run side by side with the nationalisation of education; and it is probable that when the advantages accruing from Sanitary Science, taken in the broadest acceptation of the term, become better known, the prospects of Irish Public Health administration will become much brighter.

It has with truth been said that panic is the parent of sanitation, and if we look back to the history of public health legislation for the past half century or more, we must recognise the force of the remark. So recently as last year, when these countries were threatened with an outbreak of cholera, the comparatively brief sojourn of this dreaded malady amongst us was due to a maximum of increased sanitary activity.

The sanitary defences of the country were so thoroughly and rapidly organised that the complete stamping out of this dreaded malady was accomplished in a short time, and it will be admitted that this rapid "stamping out" was a distinct triumph for State Medicine, and proves what efficient Public Health administration can achieve, and, moreover, marks with emphasis the advances that have been made since the former cholera outbreak of 1866; and in this connection it may be mentioned that the International Sanitary Conference which met at Dresden last autumn, and has now resumed its sittings at Paris, is also a distinct landmark in the history of State Medicine, being the first time for many years that concerted action of this nature has been taken by the British and Continental sanitary authorities.

The Infectious Notification of Disease Act of 1889 also marks an important stage in Public Health development in our time, as the exact localisation of disease, especially of an infectious character, is the very essence, and is a direct aid, to effective sanitary administration; the very fact of the notification of an infectious disease in a crowded population, must have far-reaching and beneficial results. To ensure these results in their entirety, compulsory powers are necessary, and had the Act in the first instance carried with it compulsory clauses, the interests of local public health administration would have been much better served.

It is much to be regretted that the Housing of the Working Classes Act of 1890 has not been availed of as largely as might have been expected; to an extent this might have been anticipated, as far as Ireland was concerned, for our local bodies are not so easily moved to take action in questions that they consider may involve a large outlay. They take, as it were, a long time to develop new ideas, and much prefer to allow matters to remain as they are, or rather as they found them. Boards of Guardians are keenly jealous of their local reputation in this regard, and appear to consider it to be their first duty to economise the expenditure of public monies, even at the expense of the health of their constituents. Urban sanitary authorities err in the same direction, and are fearful of embarking on any scheme of sanitary reform that may involve them in a conflict with the ratepayers, thus, the Housing of the Working Classes Act remains to an extent inoperative, with the result that the percentage of towns that have availed of its provisions are comparatively small. It seems, however, probable that in the near future, when the benefits of the Act become better known, it will be more generally adopted.

The position taken up by boards of guardians as sanitary authorities, has been very accurately described by Sir Francis MacCabe, who has had a lengthened and varied experience of these public bodies. At the Congress held in Dublin, under the auspices of the Sanitary Institute, in 1884, after referring to these bodies as administrators of the Public Health Acts, and after bearing testimony to the readiness that they had evinced to make due provision for the protection of the public health according to their lights, he said—"There can be no doubt that very imperfect knowledge is possessed by boards of guardians on the subject of the economy of sanitation as a security against disease, suffering, and death. They have never had any precise information placed within their reach respecting the amount of preventible disease, suffering, and death, with consequent loss of wage-earning or productive power, which may be avoided by the provision of suitable drainage and pure water. They have regarded only the direct cost, without taking into account the indirect gain, which I believe would fairly more than counterbalance the much dreaded taxation."

The condition here described has, to an extent, undergone some improvement, but even yet the sanitary authority throughout the country takes a considerable time to move in any measure of health reform. For instance, the question most vital to all, of a pure water supply, is approached in a lukewarm manner, and in some instances it has taken years to convince some of the largest corporations of the necessity of procuring water from a pure source. At the present time the vast majority of towns in Ireland depend for their water supply upon wells, mostly of a shallow nature, and liable to soil pollution, although the danger is pointed out that these sources are easily contaminated and dangerous to health, the sanitary authorities evince no keen desire to improve matters. They may be advised, and, mayhap, appear convinced, that one of the very first essentials for the healthy life of any community is an abundant supply of pure water, yet, when, it comes to the question of the outlay, they are loth to proceed further, and they postpone its consideration for an indefinite term. The wholesome dread of an outbreak of infectious disease is a potent educator, and it is remarkable how intensely active our urban and rural sanitary authorities become when they realise the possibilities of their being overtaken by some epidemic of infectious disease. A chronic condition of scare would do much to urge on promptly those health reforms so much required in the country.

(a) Abstract of an Inaugural Address delivered on Feb. 9, 1894, at the opening meeting of the State Medicine Section of the Royal Academy of Medicine.

The State inspection of industries is a branch in which improvements have been much needed, though the inspection of the conditions of health in occupation is still in a rudimentary form amongst us, as evidenced by the fact that there are yet a large number of occupations absolutely free from inspection. Women's work, until very recently, was never considered as necessary to be included in the duties of an inspector, and it was only last year that women inspectors were appointed, in two instances, to aid in the administration of the Factory and Workshops' Act. There is annually a large sacrifice in human life through accidents, unwholesome trades and occupations, which might to an extent be avoided. In England, of 527,000 persons employed in coal mining, 100,000 are disabled for a longer or shorter period every year, and there are about 1,000 killed. Now, taking this one branch of industry alone, does it not seem probable that a closer system of inspection is necessary, and a more complete and thorough supervision indicated. It has been over and over again pointed out that the number of industrial inspectors is so absolutely inadequate, that they take years to get through a cycle of their duties, the consequence being that certain occupations and trades go absolutely free without inspection for very long periods.

The establishment of county councils in England has been a decided impetus to the advancement of State Medicine, and the Bill now before Parliament, known as the Parish Councils' Bill, will also to some extent affect the Public Health Administration.

The Goulstonian Lectures

ON

THE PHYSICS OF THE CIRCULATION.

Delivered before the Royal College of Physicians at the Examination Hall, Victoria Embankment, on Feb. 27th, 1894.

By PAUL M. CHAPMAN, M.D., F.R.C.P.Lond.,
Physician to the Hereford Infirmary.

ABSTRACT OF LECTURE I.

THE lecturer began by saying, it would be impossible to treat the whole subject of the "Physics of the Circulation" in three short lectures, and some explanation is due from me as to the selection of my title, for which I must ask your indulgence. The aim of these lectures is to commend as strongly as possible a more close and accurate observation of the state of the circulation in the sick than is now employed in clinical medicine. The cardiograph has practically never been used by physicians, while the sphygmograph has fallen into disuse. The indistinct and largely imaginative use of the senses of hearing and touch has led to the disuse, and in England to the distrust, of accurate instrumental measurement in medicine in favour of the employment of what we like to call our "own unaided observation." I believe that partly reluctance to take trouble and partly the sense that our own individuality, rather than great accuracy in diagnosis, is the main factor in creating what is known as a successful practice, have more to do with this feeling than we are ever likely to acknowledge to ourselves. Be this as it may, it is the conviction of others besides myself that the employment of the cardiograph alone may give us definite proof of conditions otherwise not recognisable—still more, that the combined use of the cardiograph with the sphygmograph may be the only means in certain cases of arriving at a definite diagnosis. It is especially for the latter method of observation that these lectures are intended to be some preparation, and this can only be done by entering somewhat largely into the subject of the "physics of the circulation," which will be dealt with in a kind of summary of our present knowledge. The graphic representation of the arterial pulse and its relation to the cardiographic tracing can then, and then only, be properly discussed. It will be found, in the course of these lectures, more convenient to consider the cardiographic tracing first by itself separately in connection with the intra-cardial variations of pressure, and again secondarily in connection with the pulse tracing. In discussing the mechanism of the circulation it is of the first importance to accustom the mind to regard all changes in blood flow through any particular blood-vessel or cavity as conditioned by variations of pressure. To say that during ventricular contraction the atrio-ventricular valves are closed, and that consequently the blood is forced out of the heart into the arterial system, may be correct in fact, but it is a mode of expression not so helpful to the understanding as to say that, owing to certain detailed circumstances, the intra-ventricular pressure is raised so far as to preponderate over the pressure in the aorta. I shall therefore, whenever possible, speak of blood flow in any individual as being immediately conditioned by variations of blood pressure, though, in comparing different individuals, it must never be forgotten that a stream meeting with little obstruction may, with less driving power behind it, attain the same velocity as a stream driven with much greater power if the obstruction is correspondingly great.

Before proceeding to the consideration of clinically observable conditions it will be necessary to review shortly the state of our physiological knowledge at the present date—(1) as to the state of the heart and its contents during a revolution, and the mode of production of the heart sounds, (2) the effect on the circulation of contributory influences such as respiration, at which part of these lectures some words on the venous and capillary circulation will be convenient, and lastly (3) as regards the sequence of events within the arteries, the sphygmographic tracing, simultaneous tracings, and the use of the combined method. A full historical account of our gradual advance in knowledge would not here be possible. It will not even always be possible to pause in order to give my acknowledgments to those who have furnished me with facts. I can, however, at the outset refer to Marey's initiative work in France; to the works in German of v. Frey and Krehl, and of Hoorweg, of Utrecht, and especially to the valuable articles of Hürthle, of Breslau (*a*), and to the exhaustive summary by Tigerstedt (*b*); and in England to the physiological work of Burdon Sanderson, Waller, Roy and Adami, and others, and others, and to the suggestive clinical observations of Broadbent, Ewart, and Douglas Powell. The latest contribution to the study of the mode of production of the first heart sound is furnished by Kasembek (*c*) by experimental inquiry conducted in the laboratory of Joh. Dogiel, of Kasan, who had in 1868, in conjunction with C. Ludwig, made experiments of the following nature. They took a dog, opened its chest, and one after the other tied the upper and lower venæ cavæ, the pulmonary veins, and lastly the aorta. The heart was then excised and immersed in a retort filled with defibrinated blood, and the narrowed end of the retort was closed with an elastic membrane and connected with the elastic tube of a König's stethoscope; under such circumstances the heart, when contracting normally, gave rise to a sound. Dogiel and Ludwig therefore argued that the noise by the contracting muscle plays the most essential part in the production of the first heart sound, the system of many branched bundles of muscle superposed in layers giving a tone or noise by their sudden contraction. In 1869 Guttmann and Rosenthal, repeating these experiments, considered the sound obtained to be hollow and toneless in comparison with the normal sound, and thought that for its production the contraction of the papillary muscles would be sufficient, by whose means the valves were put into vibration but not closed. Guttmann concluded that the first sound was a mixed one and was chiefly caused by the tension on the valves, and secondarily through muscle contraction. Von Bayer, in 1870, by connecting a glass tube with the ventricle through the aortic opening and suddenly letting

a column of water into the heart, obtained a sounder, shorter, duller, and higher-pitched than the first heart sound. Since this sound strikingly differed from the normal, he concluded that the first heart sound was a muscle sound. Ostroumoff, in 1873, criticised Dogiel and Ludwig's experiments, saying that in them the heart was not wholly emptied of blood. When this was done he obtained no sound at all which could be heard through the chest wall. In a further series of experiments he excited the heart by electricity and could not thus satisfy himself of any dependence of the heart sounds on muscular contraction. The opponents of the muscle theory make chiefly two objections to the supporters of it—first, that the heart has never been so completely emptied of blood as to avoid the possibility of sudden valvular tension; and secondly, that the muscular bundles of the ventricle are not in a condition to produce a tone, since the heart contraction is not tetanic, while Helmholtz has proved that only tetanic muscular contraction produces a tone. With regard to the last objection, the bundles of muscular substance in the ventricle cross and recross each other, and are so overlaid one upon another that on sudden contraction it is quite possible that they could give rise to a sound and not merely to a rustle. Kasem-Bek's experiments seem to be fairly conclusive with regard to the first objection. They were of two kinds. First, a dog's heart was rapidly removed and, with the apex uppermost, was slightly compressed in the hand. It was then put into the retort apparatus described by Dogiel and Ludwig. Since, according to Guttmann, the valves might be made tense even in a heart emptied of blood, Kasem-Bek excised a portion of the auricular wall and thrust short gutta-percha tubes shaped like ear specula into the auriculo-ventricular openings, with the funnel-shaped expansion above and the narrow ends within the ventricles; these were either fixed in position by pins or by closing the auricles over their expanded ends. After every experiment he ascertained that no blood was in the ventricle. When the heart was now auscultated he heard, with strong and regular sontractions, a loud and well-continued tone which differed little from that heard over the apex before the experiment, except that the sound was louder in the excised heart. In his second series of experiments, with the heart *in situ*, he opened the pericardium and passed one index-finger round the aorta and pulmonary arteries, the thumb being in front at the auriculo-ventricular limit. When thumb and finger were compressed so as to prevent blood entering the heart there were heard on auscultation through the uninjured chest wall on the left side a first and second sound once; then the second sound disappeared, while the first sound persisted, though less loud than before. Krehl (*a*) comes to the same conclusion as Kasem-Bek. The consideration of the first sound as a muscle sound persisting in a measure throughout the systole originated with Turner in 1829, and the same view was held by C. J. B. Williams and the committee of the British Association in 1836. It is, I think, after the experiments I have related, as far as possible proved that the first sound is a muscle tone, to which, indeed, other sounds are superadded, especially those arising from the vibrations of the mitral and tricuspid valves, also from the vibrations of the semilunar valves, and from the vibrations of the blood column immediately above them. With regard to the second sound, it will suffice to say that it disappears when the valves are destroyed, and that it consists of two sounds united, due respectively to the closure of the semilunar valves and to the vibrations of the blood column above them. We have, of course, two first and two second heart sounds, for sounds are conveyed by both sides of the heart. These, under normal circumstances, are always heard synchronously. A reduplication of sounds, when heard, is most frequently in connection with the second sound at the base of the heart; and it is to be remembered, as has been shown by Roy and others, that the distensibility of the pulmonary arteries is greater than that of the aorta, and that the blood pressure therein is both lower and subjected to more frequent variations owing to the disturbances due to respiration. The first sound being a complicated sound chiefly due to contraction of muscles, the fibres of which are common to both ventricles, a true reduplication of it is never heard. An interesting case of apparent reduplication of both sounds will be discussed when the graphic representation of the heart's movements is under consideration. The first sound of the right heart is best heard near the right edge of the sternum, in a limit between the fourth intercostal space and the fifth rib, and the first sound of the left heart in the fifth left interspace or in the fourth intercostal space directly above. The second sound of the right heart is best heard near the edge of the sternum, in the second left intercostal space, and the second sound of the left heart at the right edge of the sternum, at the limit of the first rib and second intercostal space. Vierordt (*a*) by placing between the ear and the chest wall a column of thin indiarubber discs and estimating how many of these discs would have to be interposed before the sound vanishes, has judged the relative intensity of the heart sounds. It appears that the first sound is relatively louder on the left side, especially in childhood, and that the second sound, on the contrary, is considerably louder over the pulmonary artery, diminishing up to the age of forty. After that age the aortic second sound becomes slightly louder than the pulmonary second sound. We must assent, I think, to the summing up of Tigerstedt: "So much is certain, that our theory of the normal heart sounds, and, in dependence therewith, our explanation of heart murmurs, is still in many essential points confused, and not to be depended on for the more delicate diagnosis of organic heart lesions."

As to the production of the apex-beat we have to consider the changes of position and of form of the heart during systole.

Contrary to the generally accepted view the apex-beat is stated by Mariannini and Namias (*b*) in the 86 per cent. of women and in 62 per cent. of men to be situated in the fourth intercostal space. I think this cannot be so with English people, with whom the apex-beat is certainly more frequently felt in the fifth intercostal space. The apex tends to fall away from the chest wall when the patient is lying flat on his back. When in this position, if he rolls over on to the right side the apex-beat may disappear under the sternum. If he rolls to the left the apex comes most closely into apposition with the chest wall. On this account, and because when so lying the respiratory movements of that side of the thorax are limited, the last is the most convenient position for taking cardiographic tracings, the left arm being flexed and the palm of the hand lying under the left cheek. The apex-beat is caused by the sudden hardening of the heart in contraction against its contents, and by the apex being thrown forwards and upwards as the heart rotates on its own axis to the right, while the apex comes into a perpendicular with the basal openings. For the reasons which I have already given we can exclude the participation of extension and recoil of the aorta. The base of the heart may indeed approach the apex in systole, partly owing to these causes, but the apex is not thrust against the parietes of the chest by this means. A distinct apex-beat occurs in an excised heart emptied of blood, though the tracing, it is true, obtained from a bloodless heart is not the same as when blood is circulating through it. The tracings of the apex-beat is, by comparing it with tracings taken from the wall of the exposed heart, shown to be a tracing of ventricular muscular contraction. How far this is modified by the blood pressure within the ventricles becomes a matter of exceeding interest, the question whether the heart tracing is any guide to a knowledge of intra-ventricular states being all-important if it is to assist us in our physical examination of the sick. The general correspondence of synchronously obtained curves of ventricular contraction and of intra-ventricular blood pressure is so close as to be in favour of the view that a ventricular apex curve, or "cardiogram," is indeed, to some extent, a curve of intra-ventricular pressure.

Selected Prescriptions and Therapeutic Notes.

73.—Useful in Painful Dyspepsia :—

℞ Bismuthi subnit, gr. x ;
Magnes carb. gr. xv ;
Liq. potassæ, ♏x ;
Acid hydrocyan, dil, ♏iij ;
Tinct. zingiberis, ♏v ;
Aq. menth. pip., ad. ℥j.

M. For one dose. To be repeated twice or thrice daily.

74.—A Cardiac Stimulant :—

℞ Tinct. strophanti, ♏xl ;
Tinct. zingiberis, ʒj ;
Syr. simplicis, ʒiss :
Aq. chloroformi, ad. ℥viij.

M. Two tablespoonfuls three times a day.

75.—An Application for Eczema :—

℞ Ol. amygdalæ dulc :
Glycerini, āā ʒiij. ;
Zinci oxidi, ʒiss.

M. Rodet.

76. A Good Nutrient Enema :—

℞ Egg, one ;
Fresh milk, 4 ounces ;
Pancreatic solution, 2 drachms ;
Bicarbonate of sodium, 20 grains ;
Boiling water, 2 ounces.

Switch the egg and milk thoroughly together, add the pancreatic solution and bicarbonate of sodium, then the boiling water, and let stand in a warm place for half an hour. A little brandy or wine may be added, if desired. The addition of a few drops of laudanum frequently assists in the retention of the enema. — *Pharmacopœia of the Edinburgh Royal Infirmary.*

77. Caustic for Nævi, Tuberculous growths, &c. :—

℞ Sodii ethyli, ʒj ;
Alcohol, ℥j.

M. Apply with care. Richardson.

78. The following will be found useful in promoting the contraction of Fistulous Tracts :—

℞ Camphoræ, ℥j ;
Salolis, ℥ss ;
Etheris, ʒj.

M.

79. For Uterine Hæmorrhage :—

℞ Extract cannabis indicæ, gr. viij ;
Ext. ergotæ, ℥j. ;
Ext. hamamelis, ℥ss ;
Tinct. cinnamoni, ℥ss.
Aq. ad. ℥iij.

M. Two tablespoonfuls every three hours.
Montgomery.

◆

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows :—Calcutta 33, Bombay 35, Madras 51, Paris 19, Brussels 17, Amsterdam 21, Rotterdam 20, The Hague 17, Copenhagen 18, Stockholm 20, Christiania 23, St. Petersburg 30, Moscow 30, Berlin 20, Hamburg 15, Dresden 22, Breslau 26, Munich 24, Vienna 25, Prague 33, Buda-Pesth —, Trieste 29, Rome 23, Turin 38, Venice 33, Cairo 52, Alexandria 59, New York 22, Brooklyn 20, Philadelphia 21, New Orleans 26.

Clinical Records.

JESSOP HOSPITAL FOR WOMEN, SHEFFIELD.

Case of Uterine Polypus—Removal by Chain Ecraseur.

Under the care of John H. Martin, M.D.
Hon. Medical Officer.

Eliza C——, æt. 19, unmarried, admitted to hospital March 17th, 1890. Commenced to menstruate at the age of 16. Shortly after first menstruation she noticed a small lump between the labia. Menstruation occurred irregularly about once a month ; not much pain ; a good deal of loss ; discharge lasts from 4 to 5 days. In the interval, an offensive leucorrhœal discharge came away ; this was occasionally coloured. She had not much pain, a little in the back, and occasionally in passing water.

On examining the abdomen, a small lump about the size of a marble was found just above the pubes, rather to the left of the middle line. The lump was movable and tender to the touch. Per vaginam.—A papillomatous growth was seen projecting between the labia, purplish in colour, and soft and fringed. On passing the finger in, this was found attached to the cervix.

April 8th.—I removed the growth by means of the chain ecraseur. There was but very little hæmorrhage. The weight of the polypus was 13 ounces ; it appeared fleshy in parts, and cystic in others. The cysts, when opened, presented smooth walled linings and contained [gelatinous viscid material, probably mucin.

After the operation, the vagina was packed with pledgets of wool covered with vaseline and iodoform. These were removed next day ; very little bleeding ; the vagina was ordered to be washed out several times daily with solution of carbolic acid, one part in fifty. The patient did well, and was discharged cured on the 22nd of April.

A section of the growth, under the microscope, showed the tumour to be simple papilloma of the uterus undergoing fatty and myxomatous degeneration.

◆

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, Feb. 21st.

Dr. T. S. Clouston, President, in the Chair.

ADJOURNED DISCUSSION ON INTRACRANIAL SURGERY.

After the exhibition of cases by several members of the society Dr. John Duncan continued the discussion. He spoke largely as to the physics of brain disease and injuries, and laid stress on the importance of the cerebro-spinal fluid as a factor in intra-cranial surgery. Sudden loss of the fluid, as in spina bifida, proved fatal, less sudden loss did not, and the fluid which escaped was very rapidly secreted again. If it was easy to explain the results of decreased pressure of this fluid on the brain, it was much more difficult to explain the cause and effect of increased pressure as in hydrocephalus and alcoholic œdema. If the increase was permanent it was incurable, if temporary it could be cured. Draining in such cases was requisite.

Dr. Byrom Bramwell summed up his experience of intra-cranial tumours under the following heads :—(1) The number of cases which could be successfully operated on was few ; (2) the symptoms were often very vague ; (3) these symptoms in a small number of cases were misleading, as, for instance, tumours affecting the basal ganglia, the pons, the corpus callosum, or the cerebellum. Iodide of potassium often relieved many of the symptoms, and, although operations did undoubtedly help in many cases, yet the cure remained imperfect, a scar persisted, and dementia or other form of insanity often came on. Eight per cent. of the 10,115 autopsies of which he had notes were intra-cranial tumours. Of these one had presented no symptoms during life, eighteen no local symptoms ; in thirty no operation could be attempted, in seventeen treatment produced temporary improvement, in seventy-four out of seventy-nine on whom operations were performed success could not possibly have followed ; in twenty-eight cases which he had seen as a pathologist, in only one could a successful operation have been possible. It was, therefore, comparatively rare to find a case suitable for operation except simply as a palliative measure, and to relieve such symptoms as headache and convulsions. In local depressions and injuries, and in idiopathic epilepsy, if there was a definite and localised aura operation was called for, as also of course in abscess of the brain.

Dr. Batty Tuke said that in cases of intra-cranial pressure, non-traumatic in origin, the dura bulged more than in traumatic cases, and a layer of fluid could be seen. The operations were justified by their results, and it should be remembered that slow and gradual drainage was absolutely necessary.

Dr. Clouston said that fluid between the dura and arachnoid meant an absence of or a decrease in pressure. He was doubtful if there was any increase of pressure in general paralysis of the insane, either at the beginning or the end, except as a hyperæmia.

Professor Chiene demonstrated his method of determining the various localising points with the view of operation. He believed it better to go by proportions than by fixed points and distances. Two skulls were exactly the same, but proportionally the points aimed at were very similar.

Dr. Stien gave an account of Professor Kochu's method of ascertaining the centres on the outside of the cranial vault by means of angles, and showed that it gave the same results as Prof. Chiene's.

Drs. Cathcart, Caird, Miller, and Hodsdon spoke, and Prof. Annandale summed up the whole discussion.

◆

LARYNGOLOGICAL SOCIETY OF LONDON.

Meeting held Feb. 14th.

Felix Semon, M.D., F.R.C.P., President, in the chair.

Tubercular Tumour of Larynx.—Dr. Clifford Beale showed a patient, æt. 22, who had been under observation for the last four years, suffering from chronic tubercular disease of both apices. The throat had at first been affected with occasional attacks of simple laryngitis. During the last year a nodular swelling had formed at the posterior part of the right arytænoid cartilage, projecting into the larynx and covering the right processus vocalis. It was smooth, rounded, and not ulcerated, and only gave rise to occasional hoarseness. The firm character of the swelling, its position, its relation to the inactive disease in the lung, and the fact that it showed no tendency to disintegration placed it in the class of conglomerate tubercular tumours of the larynx described by Stoerk and others.

Complete Paralysis of the Right Vocal Cord.—Mr. Butlin showed a patient with complete paralysis of the right vocal cord. The cord stood almost in the middle line, and its free border was incurved. The other vocal cord moved well, and came in contact with the paralysed cord, but the voice was gruff and unsteady. There were no signs of disease in the interior of the larynx, and the two cords were quite white and clean. The patient said he had become gradually hoarse in the course of June, 1893. At St. Bartholomew's Hospital a careful examination had been made, in order to discover a cause for the paralysis, but without success. There were no evident signs of central or peripheral nerve lesion, no signs of aneurism or tumour in the neck and chest, no signs of malignant disease of the larynx or œsophagus. There was a history of venereal disease many years (thirty) previously, but no clear history of syphilis. The man stated that he had lately lost a stone in weight, but that was apparently only due to a sharp attack of influenza. No physical signs of affection of the apices of the lungs were discovered. The patient was a miller, æt. 52.

The President thought it possible that the paralysis might be the forerunner of tabes. He had been struck with the frequency of early abductor paralysis in cases of commencing tabes, but agreed that in the present case no symptoms were as yet evident which could justify such a diagnosis.

Carcinoma of Right Side of Larynx.—Mr. Butlin also showed for Mr. Bowlby a man, between 40 and 50 years of age, with considerable swelling and ulceration of the right ary-epiglottic fold and right half of the larynx, which was immovable. There were enlarged, hard, fixed glands on the right side of the neck, particularly below the angle of the jaw. The larynx was broader than natural. The patient suffered much from pain, dysphagia, and occasional sharp attacks of dyspnœa. His whole symptoms dated from September, 1893, when he first began to experience pricking sensations about the right side of the larynx.

Rhinitis Fœtida, with Aural Disease and Hypertrophy of Uncinate Process and Mucous Membrane covering it, simulating so-called "Cleavage."—Dr. Wm. Hill showed this case. Miss G., æt. 45. History: The fœtid rhinitis was of five or more years' duration, and had been treated by removal of crusts, antiseptic sprays and douches, galvano-cautery, trichlor-acetic acid, iodol ointment, &c. In January, this year, an attempt was made to drain the antrum through a tooth socket. A considerable quantity of pus escaped through this opening. The antrum had been syringed until within the last week, when the operation became too painful. Rhinoscopic appearance: In the right nostril could be seen the condition corresponding to the descriptions of "cleavage" of the middle turbinated body (Woakes). The body on the outer side of the cleft in this case was clearly a pathological enlargement of the uncinate process of the ethmoid, together with the mucous membrane covering it. The cleft was choked with granulations, and it was inferred that the antrum contained granulations or polypi, or some other diseased condition of the mucous membrane. Proposed further treatment: 1. Removal of the hypertrophied area ("uncinate body"). 2. Opening of the maxillary antrum through the canine fossa. 3. Establishing an accessory opening between nose and antrum, either in middle or inferior meatus.

Obscure Pharyngeal Ulceration in a Case of Arrested Laryngeal and Pulmonary Tuberculosis.—Dr. Felix Semon showed the case of N. W., æt. 36, a gentleman who, coming of a healthy family, began to suffer with severe sore throat in August, 1892. Had never had syphilis. In November, 1892, he was found to have considerable ulceration of the epiglottis. In December, 1892, Dr. Davison of Bournemouth pronounced distinct disease of right apex. He treated the larynx with lactic acid, and ordered constitutional measures. The throat got gradually better, and in April, 1893, the laryngeal ulceration had been definitely arrested. In June, 1893, the soreness started again, and the patient consulted Dr. Semon, who found consolidation of the right apex and tubercular tumefaction and ulceration of the epiglottis. The epiglottis was treated by energetic curetting followed by applications of lactic acid (30 to 50 per cent.), and the ulceration again healed, leaving a large loss of substance about the middle of the part, covered by a peculiarly white scar. The right half of the epiglottis has ever since remained tumefied. Internally the patient was given, and had ever since taken, large doses of creosote. The condition of the right lung had remained perfectly stationary, and the general health very good. At the commencement of this year Dr. Davison observed on the posterior wall of the pharynx some small, well-defined, clean, steep ulcers, which he at first was inclined to look upon as tubercular, but which did not yield to lactic acid. The patient stated that he had once before had a similar ulceration, which gradually disappeared.

Mr. Symonds suggested that the pharyngeal ulceration should be curetted and treated with lactic acid.

The President had used lactic acid without any result, but not after curetting. The fact that the larynx had healed under lactic acid made it appear that the pharyngeal condition must be due to some other cause besides tubercle.

Œdema of Arytænoid Mucous Membrane of Uncertain Origin.—Dr. Scanes Spicer showed J. F., æt. 51, labourer. First seen January 23rd, 1894. Symptoms: Shortness of breath; feeling of choking and suffocation; paroxysmal cough; excessive secretion of frothy mucus; constant discomfort in throat day and night; voice weak, but not otherwise affected; difficulty of swallowing extreme; had lasted two years, during which there had been wasting, occasional bronchitis, and slight hæmoptysis, but no positive physical signs in the lungs. Laryngoscopic examination: Pale, glistening, semi-transparent, bladder-like swelling filling upper orifice of larynx, and obscuring glottis completely. After cocainisation this swelling somewhat subsided, and the left pyramid was seen to be œdematous and lobulated. The left ventricular band was considerably infiltrated and red, but no ulceration could be made out, and it overlapped the left vocal cord. Both vocal cords moved normally on phonation, and glottis widened at inspiration. The diagnosis appeared to lie between—1. Perichondritis with secondary thickening and œdema. 2. Malignant disease with secondary œdema. 3. Tertiary syphilis with secondary œdema. 4. Tubercular disease with secondary œdema.

Multiple Sarcoma.—Mr. W. R. H. Stewart mentioned the case of F. P., a fireman, who had been exhibited by him at the first clinical meeting of the Society in April, 1893. At the suggestion of two or three members Mr. Stewart had pushed the arsenic treatment, and within a month the patient was taking liq. arsenicalis ♏xv, t.d.s., and sometimes even larger doses. The result as far as the tumour were concerned was marvellous. The glands in the neck gradually got softer and disappeared; the edges of the ulcers seemed to melt away, and the nasopharynx became fairly free. About six weeks after commencing the arsenic his fingers and toes began to feel numb, the feet swelled, his knees began to give way, and he fell on them occasionally when walking. The arsenic was then left off until July 4th, when it was recommenced, but it could not be continued in such full doses again. The trouble in the throat had gradually become worse, until it had reached its present condition, viz., much the same as it had appeared last April.

Retraction of Alæ Nasi—Ozæna.—Mr. W. R. H. Stewart showed the case of M. H., who for the last eight years had had a bad smell from the nose, gradually getting worse. The nose became blocked and very sore. As the soreness passed away the sides of the nose fell in. On examination there was a contraction on both sides about half an inch from the opening. The patient had been under treatment for ozæna for about a fortnight with applications of lactic acid, 80 per cent. solution, and the passage of nasal bougies. Mr. Stewart had not much hope of greatly benefiting the contracted condition of the openings.

Absorbed Gumma over Right Arytænoid Cartilage—Impaired Movement of Vocal Cord.—Dr. Hale White showed this case—Ed. S., æt. 33, who had frequently been under treatment at Guy's Hospital for syphilis. In December, 1893, he lost his voice; difficulty of breathiug had slowly come on, and any slight excitement brought on choking attacks. On admission cyanosis, enlarged glands in neck, specific scars on legs, perforated nasal septum; voice very husky; cough difficult. Inspiratory stridor so bad that tracheotomy appeared imminent. Larynx did not move much. Some sucking in over lower part of chest. Any excitement increased the dyspnœa. Over the right arytænoid was a rounded, greyish, œdematous-looking swelling as large as a Barcelona nut. The right arytænoid could be seen, but the posterior part of the laryngeal aperture was blocked by the swelling; the right cord moved, but not the left. Under treatment with gr. x of pot. iod., gradually increased to gr. xxx ter die, and ½ gr. of perchloride of mercury injected into the gluteal muscles, the swelling slowly subsided, and now there was scarcely any swelling, but the left cord moved but little.

Dr. de Havilland Hall mentioned a similar case where tracheotomy was often threatened, but where the use of iodide again and again averted its necessity. Tracheotomy was finally unavoidable, and subsequently thyrotomy had to be performed. The patient died of pneumonia somewhat later, and the laryngeal disease was found to be malignant, although it had apparently healed on several occasions.

The President thought that while it was not well to wait too long for tracheotomy, it was always advisable to use iodide and mercury in the first instance if possible. Cases had occurred of rapid improvement by such means. In some cases the disease had been seated in the trachea, and a too hasty tracheotomy would only have complicated matters without giving relief.

Gummata of Epiglottis (?).—Dr. Willcocks showed a patient, R. C., æt. 27, a Covent Garden porter, who had contracted a primary sore three years ago, followed by slight sore thoat and erosions on edges of tongue. Rash on skin. Voice husky for last two and three-quarter years; affected shortly after primary sore. Present condition: Epiglottis much thickened and irregularly nodulated; somewhat fixed; no visible ulceration; feels hard; view of interior of larynx imperfect; no enlarged glands to be felt under jaw.

Mr. Stewart referred to a similar case which cleared up under the use of iodide, but with occasional severe laryngeal spasm, necessitating the use of an anæsthetic. In another case the disease simply went from bad to worse, the iodide showing no result.

Dr. Bronner advised the use of mercurial inunction.

Dr. Willcocks proposed to treat the case with iodide and mercury.

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Dr. Donald Hood, President, in the chair.

Case of Hæmophilia.—Dr. Neville Wood showed a male child, æt. 14 months who suffered with his first attack at the age of three days in the form of severe epistaxis; he had twice had melæna, and the subcutaneous hæmorrhages had been as large as a tangerine orange, there had also been frequent intra-muscular hæmorrhages. No certain articular hæmorrhages had been seen. The cause was probably slight traumatism in a subject predisposed to the hæmorrhagic diathesis. Of his progenitors the father only suffered from hæmorrhage.

Case of Myositis Ossificans.—Mr. S. Paget, in introducing this case, quoted others published, and drew attention to the great toe deformity previously described, and the history of rheumatic grand-parents.

Mr. Keetley thought it was secondary to some inflammatory action, and that this was a specific disease.

Dr. Clippingdale considered they were likely to be epiphyseal in origin.

Dr. Clemow advocated the empirical use of thyroid extract.

Case of Alveolar Cyst.—Mr. Bidwell said that this arose in connection with the stump of an upper bicuspid. was the size of a small walnut, and had existed seven months. Excision was advised.

Dr. Bennett had had a similar case, but the dentist who performed extraction had taken the case in hand.

Two Cases of Psoriasis successfully treated with Thyroid Extract.—Dr. Morgan Dockrell exhibited these:—The first, a child, æt. 12, was cured in four weeks; the treatment was ½ a tabloid three times daily at the first, later increased to one tabloid three times daily. The other case was almost cured, the treatment having lasted six months. There was no local treatment in either. Small doses answer best; those cases accompanied by debility react best to the drug; the drug must be continued as an article of diet afterwards.

Dr. Abraham had treated 48 cases, of which 18 had improved, but of these external applications were used in 13. He had now abandoned the drug for this disease.

Dr. Gardner quoted a case much improved by it.

Mr. Bidwell looked upon the cure of these cases as being likely to be the improvement seen in these cases in the spring.

Case of Myxœdema treated by Thyroid extracts.—Mr. Steer said the duration of treatment of this case was ten weeks, and consisted at first of half a thyroid daily, but in one week the patient had lost 6lbs. in weight, so the dose was reduced to half a lobe every other day. He is now quite well.

Dr. Gardner exhibited a series of photographs of a case of myxœdema which was treated by thyroid juice; the tablets were used, and the total treatment extended over about six months on account of the intolerance shown to the drug.

Hæmoptysis in a Case of Mitral Stenosis.—Dr. Chapman showed this patient, a postman who had suffered with rheumatic fever seven years ago. Breathing became difficult two years ago. He had well-marked mitral stenosis, together with hæmoptysis after exertion. No phthisis. He had improved under strophanthus and iron.

Case of Lupus.—Dr. Abraham showed this case, which he said was now relapsing after having been considered as cured by Koch's tuberculin three years ago. The same member also exhibited a girl who had been shown as a case of complete alopecia areata at the December meeting of the Society; the child now presented quite a good young crop of hair; she had been treated with germicide ointments Also a peculiar secondary syphilide.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 15TH, 1894.

The President, Mr. RICHARD FAVELL, M.R.C.S., in the Chair.

Cases of Multilocular Cysts.—DR. MARTIN showed two multilocular cysts. The first was removed from a woman, æt. 47, three years advanced in the climacteric. Tumour first noticed, about the size of an egg, three months before admission into the hospital, January 8th, 1894. When admitted the tumour extended two and a half inches to the left of the median line, and to the same extent above the transverse umbilical line, and occupied the whole of the right iliac fossa. The patient was operated upon on the 26th of January, and made a good recovery.

The second was removed from a patient, æt. 26, eight years married, one child, seven years of age last October. Patient admitted to hospital January 19th, 1894. Fourteen months after the birth of the child she had a red discharge which persisted for some years. Two years ago the periods recurred regularly every fourteen days, and lasted for the same time. Four years ago her abdomen enlarged and remained so for a year, and then disappeared whilst under treatment. A year ago it again enlarged, and the enlargement went on gradually to her condition on admission—girth 41¼ inches. The main point of interest was the difficulty of diagnosis between ovarian cyst and encysted ascitic fluid. On making section the fluid discharged was exactly the same as that found in ovarian cysts. On removal of the tumour no cyst could be found which would contain the amount of fluid discharged (23 pints). Tapping would have been of no assistance in deciding the nature of the tumour. The opposite ovary was also removed. Patient made a good recovery.

Case of Pyæmia following Subdural Abscess of the Middle Ear.—Mr. PYE-SMITH showed the right temporal bone and the lungs from a case of pyæmia following subdural abscess and septic thrombosis of the lateral sinus consequent upon old disease of the middle ear and antrum in a boy, æt. 10. The antrum was cleared, the abscess evacuated, the sinus opened and plugged with iodoform gauze, and the internal jugular vein tied in the neck soon after the patient's admission to the hospital, but unfortunately rigors had been occurring for a week previously, and right pleurisy commenced about the time of operation and rapidly advanced and terminated in pneumo-thorax, the boy dying on the fourth day. *Post-mortem.*—There was a stinking abscess in each lung with purulent pleurisy and right pneumo-thorax. There was no meningitis.

Mr. PYE-SMITH also showed (1) a woman, æt. 34, with a tumour of ten years' growth attached to the hard palate which it entirely covered. (2) A woman, æt. 46, with a cystic growth in the left axilla of one year's duration, and an enchondroma of the little finger of the same side which had been present unaltered as long as she could remember.

Dr. KEELING showed specimens of ovarian and vaginal cysts, cauliflower cancer of cervix, and retained placenta from a case of abortion. Remarks were made on some points of interest in the cases.

Dr. HUNT gave particulars of the cure of a severe case of psoriasis treated by tabloid extract of the thyroid gland.

Dr. KITE read the notes of a case of idiopathic tetanus which recovered.

The PRESIDENT showed an ovarian tumour which had undergone acute axial rotation.

Dr. C. CLAPHAM read a paper on

INSOMNIA.

In which after dealing with the physiology of sleep and the necessity of its periodic recurrence for the maintenance of healthy brain function, he indicated the causes leading to its suspension, insisting at the same time that though the capacity for sleep might suffer great modification by disease, yet that it was never abolished completely. He then discussed the various remedies for sleeplessness, and advocated the use of the more simple ones first, recourse not being had to the more powerful until these had failed, the more gentle the means employed to induce sleep the more natural, he considered, would be the sleep induced. Dr. Clapham objected to the use of chloral or bromide of potassium in cerebral anæmia, especially when occurring in melancholics, alcohol and opium being more suitable. He recommended pot. bromide in insomnia due to overwork, and chloral hydrate in sleeplessness with sustained high blood pressure or when distinct pyrexia was present. Of the newer hypnotics he preferred chloralamide and sulphonal. In conclusion he urged that hypnotics were edged tools which should not only be carefully used, but their abuse jealously guarded against.

France.

(FROM OUR OWN CORRESPONDENT.

PARIS, March 3rd.

TREPHINING IN GUN-SHOT INJURIES.

AT the Société de Chirurgie M. Quénu spoke on the necessity of applying the trephine at an early hour in cases of fracture of the cranium from gun-shot and not wait, as some have advised, until symptoms of meningo-encephalitis had set in; the projectile or the foreign bodies were sufficient to create infection of themselves, and consequently should be removed as soon as possible. He cited three cases in point. A child of eight years was brought to him suffering from a small wound in the frontal region caused by a fall on a stone, as was supposed. The following days the boy fell into a kind of torpor which frightened the parents, and M. Quénu was called in. On examining the patient the surgeon decided on operating, and when a piece of bone was removed by the trephine, two fragments of a small bullet were found embedded in the wound and giving rise to an abscess. It turned out that the boy had been playing with a pistol on the day of the accident. After that the wound had been cleaned out, a drain was inserted, and in eight days the patient seemed quite recovered. However, six weeks afterwards the symptoms reappeared, accompanied by epileptic seizures, and the child died.

The second case was that of a man, who after killing his mistress, lodged five revolver bullets in his head. He was brought to the hospital, where the house surgeon applied antiseptic dressing, but in spite of that the wounds gave issue to suspected liquid forty-eight hours after the accident. The trepan was applied, and M. Quénu was fortunate enough to be able to extract all the projectiles, of which two were found embedded in the temporal bone; two lay beneath the dura mater, while the fifth had perforated this membrane.

In the third case a child received a ball in the forehead from a Flobert rifle. As in the preceding cases, the instrument was applied and the wound cleaned out; the dura mater was not perforated. A week afterwards the child was able to leave the hospital.

In concluding M. Quénu said that in penetrating wounds of the cranium it is in general wise to operate at once unless the probe showed that the foreign body had penetrated to a great depth.

M. Reclus said that in his mind the surgeon should not operate unless the projectile had determined a septic condition of the wound, or when symptoms of compression are present due to a wounded vessel, or, again, when chips of bone had been carried in by the bullet.

M. Monod gave, in connection with this question, some statistics which were published by American authors. Wharton furnished an account of 316 cases of foreign bodies in the brain derived, for the most part, from fire-arms. Of this number 160 recovered; 106 times the foreign body was extracted, 72 recovered; 210 times, on the contrary, nothing was done; 88 persons recovered, 122 died. The occipital region was twice as fatal as the frontal or parietal.

Basedow's Malady.

M. Marie, in recurring to this subject at the meeting of the Société des Hôpitaux, expressed the opinion that the malady in question had not a thyroidian origin, as it was not rare to see it produced almost instantaneously under the influence of a strong emotion, and, again, that it was most frequently observed in tabes, that is to say, in one of the diseases when the nervous system is particularly affected. Would it not be consequently more rational to attribute a nervous origin (sympathetic) to Basedow's disease?

As to the treatment by the ingestion of the thyroid body, he had very little faith in it, while, on the other hand, he gave all his confidence to extraction of the gland as practised by Tillaux. Recent statistics bearing on 41 cases of myxœdema showed that thyroidectomy cured no less than 34; two died from tetanus, while the remainder did not appear to have been benefited by the operation.

◆

Germany.

[From our own Correspondent.]

Berlin, March 2nd.

Pernicious Anæmia in a Child.

At the meeting of the Medical Society of the 7th ult. Hr. Baginsky reported a case of pernicious anæmia in a child of 3½ years. The child was of healthy parentage. The year previous it had on one occasion lost a very large quantity of blood from the gums and lips. Shortly before admission into hospital violent epistaxis followed an attack of coughing, and was arrested with difficulty. On admission on Dec. 13th of last year, the child presented an extraordinary pitiable appearance, it was as pale as a corpse, and showed aphthous ulceration of the mouth, lips, and fingers. At this time a pneumonic affection came on with continued high temperature. The red blood corpuscles had diminished to 2,800,000. The hæmoglobin was 17 per cent. instead of 60, the specific gravity of the blood 1037 instead of 1057. The proportion of white to red corpuscles was 1 to 100 instead of 1 to 120. The child gradually sank with considerable gastric trouble, enlargement of liver and spleen, and dilatation of the heart. Autopsy: very fatty heart, with softening of the muscular structures, large fatty liver, fatty kidneys, firm spleen, atrophied intestines: no change in the marrow of the bones. Only sixteen cases of pernicious anæmia in children were on record.

Hr. Senator then related

Two Cases of Biliary Cirrhosis of Liver.

The first was that of a Russian merchant, æt. 46, who in June of last year had an attack of jaundice that did not pass away in spite of treatment, nor after a course of treatment at Carlsbad. The patient first came under the speaker's care in November last, with olive-coloured jaundice. He complained of weakness and intolerable itching. The liver was very large, reaching to the umbilicus, was perfectly smooth and painless; a small tumour in the region of the gall-bladder. No ascites, no venous dilatations, motions steadily uncoloured, urine markedly icteric, with very distinct biliary colouring reaction. Treatment without result. In the course of some weeks the tumour of the gall-bladder increased in size, became very painful, and at last could be felt of the size of an apple. Fever now appeared. There were no attacks of colic. On account of the threatening symptoms cholecystotomy was performed on Nov. 27th, and about 200 grms. of tolerably clear fluid evacuated. From the wound and from the gall-bladder the whole under surface of the liver could now be felt, and no cause for the blocking up of the bile discovered. Since then the liver had vastly diminished in size as far as the margins of the ribs. A resistance then appeared in the epigastrium that gave the impression of a tumour, but the appearance of the patient and palpation were opposed to the assumption of malignant disease. Latterly the supposed tumour had disappeared so that the speaker concluded it must be constricted liver tissue. The biliary fistula was completely shut off, and showed no communication with the hepatic duct or the cystic duct. At the same time a secretion took place, that at a glance would be declared biliary. How bile could find its way into the fistula could not be seen: the fluid was yellowish, slightly greenish, no proper biliary constituents could be found in it. It contained a good deal of albumen, but not a trace of mucine, no bilirubine, urobiline, or cholesterine could be found in it. The case was a typical one of biliary atrophic disease of the liver in consequence of absolute closure of the biliary passages.

The second case was that of a distiller who first became jaundiced in October, 1892. After temporary improvements the jaundice returned several times, but for a year it had been constant. The patient had never had any pain or itching, and his appetite was remarkable. Examination showed very considerable enlargement of the liver. The spleen was also very considerably enlarged, no disturbance of the portal vein, no venous stasis either in the stomach or bowels. The stools latterly always dark coloured, the surface of the liver perfectly smooth. The urine was icteric, contained no trace of bilirubine, but a large quantity of urobiline. Bilirubine was present in the blood. The case was a typical one of hypertrophic cirrhosis of the liver, with jaundice and enlargement of the spleen.

Hr. A. Fraenkel said that he saw a man eight weeks ago, æt. 40, with intense jaundice. The patient was apparently acutely attacked in August last with jaundice, rigors and fevers. On examination, in addition to enlargement of the liver, on its front border in the region of the gall-bladder was a tumour the size of an apple. Fever and rapid emaciation. No glandular swellings. On account of the emaciation the speaker concluded there was malignant disease. There was occasional rigors. Exploration was performed by Hr. Körbe, when a large pear-shaped gall-bladder was met with from which 150 to 200 grms. of turbid nonpurulent fluid were removed. There was no stone. Blunt ending of the gall-bladder towards the cyst duct. On drawing the gall-bladder aside, a tumour was seen in the neighbourhood of the hilus of the liver which gave the impression of a dilated bile duct. On opening it at least 100 grms. of sweet smelling pus escaped.

After complete removal of the pus, every part was palpated for detection of a stone, but in vain. After closure of the gall-bladder, a segment of the tumour mentioned was stitched into the wound, a large quantity of bile escaped from the fistula the first few days, the stools however remained clay-coloured. The fever subsided at first and it was planned to make an opening between the duct and the intestine. In the meantime, however, the patient died. On post-mortem examination, hydrops vesica sellæ with closure of the bladder towards the cystic duct. No calculus was present, but a small carcinoma at the opening of the ductus choledochus into the duodenum. The bile duct was dilated from this cause, and suppuration took place in consequence with fever. The speaker believed there was carcinoma in Hr. Senator's first case as well.

Hr. J. Israel said that in the first case the left lobe of the liver was very hard, nodular, and in his opinion the seat of malignant disease. On getting into the gall-bladder two tumours were felt on the under surface of the liver. One to the right the size of an apple, and one at the base about the size of a cherry. These could not belong to the liver, they must be tumours, and probably malignant tumour, had formed at the mouth of the bile duct, whence secondary nodules had formed on the left lobe of the liver.

Hr. Senator, in reply, said that when the opening was closed, the patient became feverish and uncomfortable. In view of the changes that had taken place he was doubtful of the malignant nature of the disease. At the time of the operation he had examined the whole under surface of the liver and had found nothing abnormal.

The German Dermatological Society.

The Fourth Congress of this Society will be held at Breslau on May 14th and the following days. The sittings will be from nine to half-past twelve in the morning and from two till half-past four in the afternoon. The chief subjects for discussion will be (1) Modern attempts at Systematisation in Dermatology, introduced by Prof. Kaposi of Vienna; and (2) The present position of our knowlege of the Dermatomycoses, introduced by Professor Pick of Prague. In addition, several addresses and demonstrations will be given. There will be an exhibition of instruments, drugs, casts, microscopical and pathological specimens, &c. The official language of the Congress will be German, but addresses or observations in any other language will be permitted.

Austria.

[From our own Correspondent.]

Vienna, March 2nd.

Morbid Vesicle Changes.

At the "Doktoren Collegium," Prof. Englisch showed a large number of preparations of the bladder which were not without interest. The excrescences or sacs which form on the side he divided into two categories :—(a) those containing all the layers and coverings of the bladder, which he termed pockets; (b) those where a perforation of the muscular tissue existed through which the mucous membrane penetrated and formed with the subperitoneal tissues a bladder cell. Those belonging to the first category presumably arose from some weakened condition in the wall of the bladder, usually located to the anterior parts of the ureters, the site of the urachus remains, or the posterior walls. Those occurring in front of the orificium vesicale urethræ are usually congenital, and are found in early childhood. These sacs can either be unilateral or bilateral; they may either be wide or narrow at the exit from the bladder. These are seldom found above the prostate, and only when occurring in hypertrophied bladders. They are rarely found on the upper part of the bladder. The second category or bladder cells usually arise out of hypertrophied bladders. The mucous membrane is forcibly pressed into the trabeculæ, and driven through to the outer coverings and may be found anywhere on the bladder wall having no typical position, the greatest number, however, appear to be situated on the posterior and lateral walls.

The excrescence where the opening is wide is of a conical or elliptical form, when narrow of a cylindrical form. The consistence is parallel with the thickness of the bladder. In diagnosing these changes the bladder should be full, and the width compared with the length; the percussion is often to be found unsymmetrical. It is of great importance that the rectal and bimanual examination should be conducted, while instrumental illumination should not be neglected. A catheter with a slight bend, or an infantile lithotrysee serves admirably for the instrument as this will enter the mouth of the sac and remain fixed. In these conditions urination is often interfered with, resembling stone. When the water is drawn off by the catheter, a large quantity will be emitted by slight pressure after the catheter has ceased to run. In lithiasis and prostatic hypertrophy, pain will accompany micturition, but in sac formation, no pain is present. In affections of the mucous membrane, the first portion of the urine is clear, the second cloudy, that may come from the sac. In examining the second category, care should be taken that too great force be not used, or the instrument may pass easily through the bladder cell. Clinical observation is the best diagnostic guide, and particularly the sediment, which contains phosphates, mucus, and epithelia; the patient complaining of an unusual pressure in several parts of the bladder when micturating, or its being sensitive to the touch. Frequently there is inflammatory phenomena in the region of the organ, with pain on retention. Several of these cases had acute pericystitis and peritonitis, others with perforation. In many of the pouches stones may be found, and not recognised during life, owing to the orifice being too narrow. In other cases several of these may be present. In one case which he showed, the patient had suffered great agony, and no stone could be found, the cramp condition of the bladder made catheterisation inapplicable, yet on section of the body, 28 stones were found located in one of these bladder cells. In such cases it is better to examine the bladder both when full and empty.

Hepatic Atrophy.

Dr. Foges showed a preparation from a case that had come into hospital complaining of great dyspnœa, and severe pain in the epigastrium, œdema was present, with albumen in the urine, the conjunctiva icteric. Short time after admission, he died of collapse, and the post-mortem showed acute yellow and red hepatic atrophy nephritis. Small hæmorrhages infect the spleen and kidneys with thrombii. It was presumed that nephritic disease was the primary cause, and that micro-organisms were carried in all directions where a large thrombus had been formed in the portal artery, and had produced the acute hepatic atrophy.

The Operating Theatres.

UNIVERSITY COLLEGE HOSPITAL.

Ovariotomy.—In performing this operation on a woman, æt. 57, Mr. **Barker** found the tumour to be a double ovarian; the first portion had only one or two adhesions, but the second he found jammed tightly in the pelvis, and unusually adherent to the rectum and to the back of the uterus. Luckily the adhesions could be torn through with the hand, and there were no bleeding points. On the right side four ligatures were placed on the pedicle, and on the left side two ligatures. There were no adhesions to the intestines. Mr. Barker remarked that it was easy to keep the intestines back in such cases; he could not help a little fluid getting into the abdomen during the operation, but the cavity was well mopped out, which he considered of great importance, as well as to remove all clots; he thought too it was important to avoid handling the contents of the abdomen more than was absolutely necessary, on account of the shock that might be thereby set up. In closing the wound the stitches were carefully passed on each side through the sheath of the rectus, as well as through skin, muscle and peritoneum; this the operator thought very essential, as he considered such a procedure a great preventive to a subsequent hernia; but he said it was difficult to make the abdomen as strong as before the operation, and a tentency to hernia was very likely to ensue owing to the abdomen having been so much distended.

Varicose Veins.—In operating for varicose veins, Mr. **Barker** remarked that it was best to begin at the highest point where the veins were affected in the leg, as thereby any small clot which may be in a lower part of the vessel is prevented from going upwards, also because the operation is afterwards rendered easier, as the occlusion above causes the veins below to swell and so become more apparent. He considered a short incision quite sufficient, and also that it was sufficient to remove a small portion of the vein, it being, he remarked, theoretically the same to remove a short piece and practically far worse to take a long piece. In his opinion a very great point was never to perform this operation when there were any sores or varicose ulcers about the leg. It might be asked, he said, why not merely divide the vein between two ligatures without removing any portion, but it must be borne in mind that a certain proportion of the vessel is handled by the surgeon during the operation, so it is better to excise it. He remarked that he never operated on both legs on the same day—1st, because so doing made the subsequent nursing very difficult, the patient being reduced to absolute helplessness; 2nd, because in the event of anything going wrong, when the temperature rose, it would not be known from which leg to take the dressings; therefore his invariable custom was to leave about a week between the two operations.

GENERAL HOSPITAL, NOTTINGHAM.

Congenital Hernia.—Mr. R. C. **Chicken** operated on a case of congenital hernia in a child. He remarked on the necessity of curing these cases by operation instead of by the application of pads or trusses. It was true, he said, that a congenital hernia would often disappear after the prolonged application of a pad, but was the permanency of the disappearance to be relied on? He thought not, because in many cases of so-called acquired herniæ of adults he was accustomed to find the bowel in a congenital sac He pointed out that the specimens in our museums made us familiar with the fact that the obliterated sac of a congenital hernia has only become adherent at one point, which might allow of a partial descent of the bowel into the rings and canal, or if contracted at a higher point, the constricted portion might be pushed down before it into the scrotum. The one main point he considered to be achieved in curing a congenital hernia is the destruction of the sac above the internal ring. This cannot be done with certainty by any pad or application, but by using external pressure only union is most likely to take place in the inguinal canal, consequently the bowel is allowed to keep the internal ring in a chronic state of more or less dilatation. But if the sac be destroyed above the ring its own inherent power of contraction will probably suffice to ensure its diminution to normal limits. Therefore, in his opinion, the great importance of thorough destruction of the sac above the internal ring and the minor importance of suturing the rings. As a matter of practice, however, he always did put a single stitch as an additional safeguard. There was a great deal of difficulty sometimes in defining quickly and accurately the sac of a small congenital hernia: in large varieties it was plain enough. The best plan of operation, he demonstrated, was to pinch up a fold of skin and pierce it to a sufficient depth to leave a wound large enough to complete the operation, then dissect down until the shining fascia of the sac is seen. With a few touches of the point of the knife this is sufficiently freed to be picked up by the finger. The true sac is then gradually drawn over the finger tip, being cleaned meanwhile by the knife until it is completely isolated from the cord, especial care being taken always to define the vas. The sac is divided between two ligatures, the proximal end returned into the abdomen and the ring sutured. In the case of very small herniæ in young infants, where the various layers of the sac are very delicate and not easily defined, it is equally efficacious to thoroughly split them up and tease out the slender fibrils, returning them *en masse* through the rings, for by these means the cavity of the sac is obliterated by promiscuous cohesion. It is very interesting, he thought, to remark the enormous hypertrophy which is often found in the fibres of the cremaster, as though by these means natural efforts were made to control the descent of the bowel. He pointed out that in large congenital herniæ in infants the sac is greatly thickened and developed in its fibrous texture. It is important, he said, to examine carefully and note the structure and composition of the sac in infants, for the knowledge here gained is most useful in determining the best operation in adult cases, for according to the structure of the sac must the operation be fashioned, or in a bad case the special requirements may not be so satisfactorily met by a routine system being always adhered to. Mr. Chicken strongly urged the necessity of operating in all cases of congenital and infantile hernia. The result, he said, in his hands had always been a permanent obliteration. He remarked too that he had frequently to operate in cases which had been put forward by the advocates of the "truss cure" as examples of the success of their treatment, but in which the bowel had subsequently again descended. The success of the operation, when performed in later life, was, he thought, not to be compared to that on the infant, the operation in the latter being short and simple, and the wound healing quickly. Mr. Chicken dresses the wound by keeping it thickly coated over with an antiseptic varnish, so that it is not affected by the evacuations of the patient.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 7, 1894.

THE PHILOSOPHY OF PAIN.

Pain is often, somewhat flippantly, referred to as a mystery, but if so, it is a mystery with a physiological moral. Pain is not a "thing," an evil entity, it is not even an absolute standard of sensation, for what is pain at one time may be pleasure at another, and *vice versâ*. Moreover, the same or similar causes give rise in different individuals to very different degrees of pain, or may even determine sensations more akin to pleasure, this being currently considered to be the physiological antithesis of pain. Years ago Hilton, under the attractive title of "Rest and Pain," called attention to the nature, philosophical and anatomical, of pain, and discussed, in a series of lectures which will long remain one of our medical classics, the diagnostic value of disagreeable sensations. More recently the subject has been approached from another point of view by an able and eloquent writer, Dr. Cameron Gillies, who has devoted a good deal of anxious thought and labour to the elucidation of "the meaning of pain." There is much in his unassuming little *brochure* which is calculated to interest the medical philosopher, for he enables us to contemplate the phenomenon from various points of view, and his reflections are couched in English of singular lucidity and finish. He virtually renounces the task of defining what is pain, and contents himself with discussing its manifestations and significance. What is pain to one, he observes, may be pleasure to another, and even in the same person the power of pain, meaning thereby, we presume, the capacity for perceiving pain, varies greatly at different times, and under different circumstances. What may be cause of pain and suffering at one time may after awhile become tolerable, and perhaps agreeable, and, on the other hand, pleasure soon palls and merges into pain. In fact, no strict line of demarcation can be laid down between pain and pleasure, for, as sensations, they are continuous, each merging into the other, and, at or near the hypothetical boundary line, very small things determine the balance on one side or the other. The scratch of a pin puts a man into pain, the tickling of a straw into pleasure. Even music, sweet and grateful as it may be, if continued long enough—and not necessarily for very long—becomes an endurance and suffering, a fact which most of us have had brought home to us at one time or another. Pain, as Dr. Gillies points out, involves the conception of punishment, with which medical men have nothing to do, and for this reason the term suffering is preferable. Owing to the fact that disease is not altogether an exchangeable term for pain, many abnormal conditions not being associated with pain (some, even of the most fatal kind, being quite exempt from distinctly painful sensations), a troublesome distinction has arisen between pain and disease. Yet, etymologically, disease means the contrary of well-being. Speaking generally, pain means something wrong; it is Nature's indication that at some point in this beautiful organism of ours, the physical conditions compatible with health have been thrown out of gear, thus giving us warning, and affording us an opportunity of doing something to put matters right again. A sensation of pain may remain after removal of the cause, but this serves the useful purpose of ensuring the rest, and consequently the repair, of the injury done. Nature's motto seems to be *nemo me impune lacessit*, and though art may postpone, it cannot avert, the penalties, which simply accumulate. The meaning and use of pain is so far easy to understand. It is in its every manifestation our best friend, without which guide, counsellor and friend, we should perish all too prematurely. Pain, again, has been described as the prayer of a part for food. It is so of the organism as a whole, and it is so of each of its parts, even to the smallest living cell of our organism. Defective nutrition is probably at the bottom of all acute disease that is attended with pain. It may be local, sudden and apparent, or it may affect the tissues in their minute structures, in the cellular elements, but in the latter case, it is beyond the power of the senses to measure or to observe the process in its details. Pain, then, is the prayer for food, for healthy nourishing blood to repair the injury; and the whole process of inflammation is the purposeful response to that prayer. Every detail of the process of inflammation, as also the result, clearly indicates its good purpose, and it would be difficult to over-estimate the harm that has accrued to mankind from the contrary view, that inflammation is of the nature of an evil spirit, to be exorcised at the earliest possible opportunity, at whatever cost. If, says the author, we could by any means stop inflammation before it has served its beneficent purpose, we should surely kill the patient. If we interfere with it at all, except to sustain and encourage the process, we do harm. The use of drugs to smother pain is a doubtful blessing except the import of the symptoms be fully grasped and acted upon. Pain is the *vis a tergo* of our social and moral life, the hope of a rest being the *vis a fronte.* These two forces co-operate in the same direction. Relief from pain is to be purchased only at the price of local or systemic rest. Moreover, pain is a tonic, and a very valuable tonic. It stimulates the syncopal heart and recalls the fainting organism to life and to reaction. The presence of pain is a promise of healing, a guarantee even, that there will be complete restoration with intelligent care and rest. Where there is pain there is life, and the pain attending injury or disease usually varies as the vitality—the promise of life. Finally, pain is by no means an unsearchable mystery, even though in certain of its manifestations we may not at once and clearly grasp its beneficent purpose.

◆

UNION INFIRMARIES AND MEDICAL EDUCATION.

IT is a somewhat curious fact that the scheme of modern medical education depends almost entirely upon the voluntary charities for the material upon which its practical instruction is founded. If we compare the wards of a teaching hospital with those of the large union infirmaries that often lie literally within a stone-throw of its gates the contrast is somewhat startling. In the former we find a numerous medical staff, including honorary physicians, surgeons, and specialists, together with a host of registrars, resident house physicians and house surgeons, clinical clerks, dressers, and students. In the latter or parochial building we find a limited number of resident medical officers, acting under a superintendent, or under visiting physicians and surgeons. The knowledge, however, that such inequality exists is no new thing; the waste of educational material in the Poor-law institutions has been before the public and the profession for many years, although lately it has been more pointedly insisted upon by those interested in the matter. The final report of the Lords Committee of Inquiry upon the Metropolitan Hospitals emphasised the view that the Poor-law infirmaries would form a very useful field for medical instruction. That their conclusion is correct cannot be questioned by those conversant with the environment of those places. The idea that such institutions contained nothing of more professional interest than chronic bronchitis and senile diseases has long since been exploded. The fact is that in their wards may be found all kinds of acute as well as of chronic diseases, both medical and surgical, affording an inexhaustible mine of wealth to every branch of specialism. That being the case, one need only advance the further propositions that the existing hospitals are overcrowded by students, and that it is necessary for students to have access to abundant clinical material in order that they may acquire their special knowledge of disease. On these premises it is easy to show the desirability of an extension of the present system which would permit students to avail themselves of the opportunities afforded by the Poor-law infirmaries. Some worthy people object to turning out a lot of students, as they term it, to overrun the wards of Poor-law institutions. They appear to overlook the fact, however, that such students would be working under supervision. There is no reason, moreover, why a careful selection could not be made in the first place, so as to select students who had already proved themselves trustworthy. There can be little doubt that the introduction of the teaching element into parochial infirmaries would result in benefit to all concerned. The stimulation afforded by healthy outside criticism could hardly fail to raise the standard of medical work no less than that of nursing, also of the general management. Of late years great advances have been made in our union infirmaries, and the progressive tendency has been apparent not only as regards the buildings themselves, but also as to the numbers and skill of both medical and nursing staffs. This advanced attitude is more apparent, perhaps, in the provinces than in the metropolis. It is in part, at any rate, an expression of the latter-day leaven of democratic ideas which is fermenting in and pervading the modern mind. The people, according to the ideas of the more advanced social reformers, are entitled to a fuller share of the wealth they have created than they at present obtain. Hence, in the capital of the Midlands we see a magnificent Poor-law Infirmary, where the sick poor have the advantage of the best medical skill and of the most approved modern therapeutic agents. Indeed, were the admission to such places granted under less repellant conditions, they would form a veritable haven of refuge to the disabled poor. Such a desirable state of affairs, however, is not likely to be brought about until local Poor-law administration is thrown more into line with modern progressive views. The latter assert that guardians exist to minister to the needs of the poor, and not to drive them off by that system of organised brutality which still lingers amongst us under the comprehensive title of bumbledom. In other words, the poor should receive as a right the relief that is theirs by virtue of legislation, and not as a repulsive dole to be acquired only by facing official insult and attendant reproach. The remedy for this state of things, however, must be reasoned out by the political economist and insisted upon by the people themselves. Meanwhile, it is to be hoped that an enlightened and enlightening Local Government Board will throw no obstacles in the way of opening the doors of the Poor law infirmaries to the students of the most progressive and important of all scientific studies. It is certain that the ratepayers who defray the costs of those institutions would in that case reap the benefits of a general advancement of medical skill and knowledge, which in this way would add materially to the sum total of the national wealth.

◆

THE SANITARY EDUCATION OF OUR LEGISLATORS.

One of our leading lecturers on sanitation (Dr. A. Wynter Blyth) recently dealt with the subject of sanitary laws and their administration, calling attention to the fact that far too many members of rural sanitary boards are not only ignorant of the first requirements of science, but actually possess no knowledge of Parliamentary enactments. The truth of this assertion is too often exhibited, when the best-thought-out plans of health officers are thwarted through the obstinate opposition of the majority—or only a noisy minority—of the board generally prompted by cheeseparing economy, and fostered by a want of knowledge of the very Acts which they are supposed to administer. And are not our rulers, both great and small, sadly ignorant of both sanitary law and science? Is it too much to hope that at some future date the plan suggested by Dr. Wynter Blyth should be adopted?—a time when there will be a school of legislators, the first form of which will be the Parish Council, members of which could in due course aspire to a seat on the District Councils, then to the County Council, and finally to Parliamentary honours. Of course, one effect of such a scheme would be to ensure really educated and substantial men to come forward for the parish councils, sanitary boards, &c., the very authority which have to bear the brunt of putting social and sanitary laws in force. As matters stand at present, the best intellects of the country are not usually to be found among the local elected authorities. Here and there, no doubt, men of education and position do take a sufficient interest in local matters, and a sufficiently high view of their duties as leading citizens, to induce them to become members of local or sanitary boards, county councillors, &c. But these are, unfortunately, only the exceptions to the rule. Hence the low esteem in which many such authorities are held, their incapacity, and often their potential force for harm. Abroad, stepping-stones to legislative power are recognised by custom, if not by law. Except as regards the turbulent, revolutionary or noisy journalist, the Conseiller Communal, or Municipal, generally becomes a Conseiller General before trying to gain a seat in the Chamber or Senate. And by this means we find men of university education, barristers, doctors, and land proprietors taking active part in the government of the smallest towns and villages. If they have no very great knowledge of laws, and some of them but very imperfect ideas as regards hygiene, still they are able to grasp the importance of such matters, and are open to conviction by those who know. With us, electors look for business capacities, and this often means a squalid guarding of the purse, with a marked tendency to economise in such matters as sanitary work, a work which, though costly, has apparently so little to make a show of. As matters stand now, it seems quite hopeless to expect men who are probably keeping shops or looking after their trades and businesses to make any serious attempt to master a rudimentary knowledge of the large number of Acts of Parliament relating to the health administration of the country, and for the putting in force of which they are mainly responsible. Hence arises friction between conscientious executive officers and stubborn elected men in power, to the paralysing of efficient work and the no small joy of jerry-builders and other selfish money-grabbers who are eternally on the look out how best to evade the law, to the infinite inconvenience and danger of the community at large. When we mount higher in the scale of government there is not much to encourage us. Certainly the County Councils have done nothing to win the respect of citizens widely anxious as to the health of the nation. And much the same may be said of Parliament. It is true that the majority of Members who sit in the House of Commons are men who have either received a good education or who have brought themselves into prominence through superior qualities or force of character. But the majority of Members enter the political arena when advanced in life, with fixed business or property interests, and without having received any systematic training. They are, consequently, very difficult to deal with. They regard most health questions as technical matters for the consideration of doctors, but far subordinate in importance to the smallest matter having a political bearing. Hence health enactments have to be reduced to political and business considerations: vested interests play a great part in such debates, and the merest trifle may decide the fate of an all-important clause. Carefully-considered clauses are cut up, amended, added to, and altered in such a way that their original meaning is entirely lost sight of, and, indeed, the whole passage made so obscure that when the Act becomes law there is room for abundant disputations as to its meaning. How many of our sanitary Acts are disfigured with such doubtful clauses, through which many a sinner drives his four-in-hand, regardless of the warnings of trained experts who try to stop his progress. This slovenly legislation, the direct outcome of ignorance, has, too, a bad effect on the lawyers. Health officers have been taught by hard experience how magistrates and judges will oppose them and defend evil-doers, saying "What care we for the spirit of the law?—here is the letter," though the letter of the law may be in direct opposition to the intention and whole tenour of the enactment. When the laws have been properly drafted, nursed through committee, and the dislocated body safely made whole again, there will be no room for such equivocations, and those who sit on the bench will come to recognise that sanitary laws are not meant to be legal puzzles, or devices for sharpening the wits of evil-doers against the health of the State. And so the whole thing turns on the question of education. If we cannot put all legislators through a training school such as is here suggested, some means must be sought to strengthen the hands of the highly-trained executive experts against the ignorance and financial tyranny of the administrators, while we await the gradual enlightenment of our legislators, both great and small.

Notes on Current Topics.

A Curious Dispute between Medical Men.

A DISPUTE which has, we regret to state, assumed somewhat of an acrimonious form, is now in progress between the Medical Superintendent of the Kent County Asylum, Barming Heath, and two medical men residing in Bromley, with respect to a difference of opinion regarding the condition of a patient who was recently transferred from the Bromley Workhouse to the Asylum. The facts are as follows: Complaint in the first instance was made by the Superintendent to the Chairman of the Bromley Board of Guardians to the effect that the patient in question on reaching the Asylum was suffering from a fracture of the fifth rib a short distance from its costal attachment, as well as from several contusions of the skin. This statement was accompanied with an expression of opinion that the medical officer of the Union could not have exercised that necessary amount of care in examining the patient before despatching the latter to the Asylum, as no intimation had been sent respecting the injuries which had been subsequently found. These facts were at once brought under the notice of the guardians, and their medical officer was called upon to explain them. His reply was directly denying the allegation in regard to the fractured rib, while he stated that he examined the patient thoroughly two minutes before sending the latter away. At this stage the Commissioners in Lunacy were made acquainted with the correspondence which was in progress, and after this repudiation of the Union officer, called upon the Superintendent to give his account of the case. His version was that his two assistants and himself each verified the fracture, and agreed as to its presence, and that there was no possibility of a doubt in regard to the injury. Meanwhile permission had been obtained by the guardians for the Union medical officer and another local medical man to examine the patient in the Asylum. The examination was made in the presence of two of the medical officers of the institution: the patient was palpated and auscultated over a flannel bandage and two layers of adhesive plaster, which had been applied for the treatment of the alleged fracture, and in the end the Union officer and his friend reported to the Board of Guardians that in their opinion no fracture had ever occurred. This brought the retort from the Superintendent that their examination in the manner above stated was an absurdity, and that their attempt to dispute the diagnosis was a piece of impertinence. The guardians at this juncture invited two more local medical men to examine the case and report. But under the circumstances we think it would have been much more expedient to have asked two hospital surgeons in London to give a decision on the dispute.

The Chelsea Hospital for Women.

WHAT is described by the local papers as "The Scandal at the Chelsea Hospital for Women"—a somewhat severe description—is attracting further public interest owing to the fact that dissatisfied former patients, or their friends, are now beginning to communicate their grievances to the Medical Officer of Health by whom the charges against the institution have been formulated. Two persons have written to say that their wives have died consequent upon operations performed in the hospital. In the first letter the writer stated that his wife underwent three operations without his consent, while in the second, the writer asserted that his consent had not been obtained to an operation which was performed on his wife in June, 1893, and that she died on August 5th following. The certificate of death in the latter instance was endocarditis and septicæmia, six days. Of course, any statement of this kind emanating from patients should be accepted with a great deal of reserve, until the facts have been fully inquired into. Practically speaking, the crucial point in both these cases is, not whether or not the consent of the husband was obtained to the operations, but whether or not the procedures were justifiable and performed with that requisite skill and carefulness which would be calculated to lead to a favourable result, provided that there was nothing in the circumstances of the cases to militate against that desirable attainment. The application of the Vestry to the Home Secretary requesting him to direct the holding of an official inquiry into the past management of the hospital has been refused, Mr. Asquith having intimated that it was not in his power to accede to the request. The Vestry have now further decided to forward copies of the "additional report" of the Medical Officer of Health, comprising the "revelations" above referred to, to the Home Office, to the Local Government Board, the General Medical Council, the Royal College of Surgeons, and the Royal College of Physicians. The Vestry seem inordinately bent upon enlarging the scope of their communication with public bodies. Probably on the next occasion the list will be swelled by the following: the London County Council, the London School Board, the Anti-vivisection Society, and the Society for the Prevention of Cruelty to Animals!

Amateur Doctoring.

SOME curious facts were brought to light in the course of an inquest held last week at Westminster upon the body of a women, æt. 54, who died without medical attendance. The husband, a knee-cap manufacturer, described himself as the maker of a rheumatic oil "used by all the members of the Royal Family." He stated that his wife had been ill for the last twelve months, and had been under the care of several doctors. About five months ago, however, he came to the conclusion that she was deriving no benefit from medical attention, and he decided to take the treatment of the case into his own hands. The medical evidence showed that the deceased died from bronchitis following a complication of diseases. In all probability life would have been prolonged had she been under proper medical treatment. The husband appeared surprised at this verdict, which he told the coroner he regarded as most unjust. It is really time something were done to put a stop to this dangerous practice of amateur doctoring. Here we have an ignorant man, whose connection with medical matters appears to have been confined to the making of knee-caps and the vending of a quack application, presuming to treat a woman suffering from grave internal disease. By the way, can the man's statement be true that members of the Royal Family use his rheumatic oil? Probably not; but one recalls the fact that a few years ago the Duke of Argyll posed as the grateful patient of another vendor of rheumatic applications, and that the judgment of the great ones of the earth is not always sound on the matter of patent medicines. The papers of last week report another inquest where a child was allowed to die without proper medical treatment. In that case deceased suffered from measles, which the parents did not think a serious enough malady to require the attendance of a doctor or for notification.

The Sale of Carbolic Acid.

The question of the sale of carbolic acid again came before the House of Commons last week, and Sir Walter Foster intimated that the imposition of restrictions on the sale of the drug was a matter for the Privy Council. The Local Government Board, we understand, is in communication with the Privy Council on the subject, and the matter is being still considered by the latter department. The Registrar-General has stated that since December 30th last and the 10th ult. out of twenty-eight deaths in London from accidental poisoning only one was attributed to carbolic acid, while out of ninety-eight cases of suicide seven were due to the latter drug. Apropos of this subject mention may be made of the servant girl who last week attempted to poison the household where she lived by pouring carbolic acid into the cistern from which the drinking water was drawn for the house. On analysis the amount of carbolic acid was found to be one in 40,000—admittedly not a strong dose, but still sufficient to cause inconvenience if taken in any quantity. The girl has been committed for trial.

Plastic Surgery in Paris.

A circumstantial story is going the rounds of the public newspapers, which announce a surgical operation under the sensational heading:—"Flesh taken from one man's arm to make ears for another." It is said that a Belgian was shut up in a prison cell with another inmate who was in a state bordering upon delirium tremens. The Belgian was furiously attacked by his companion, who eventually bit off both his ears. The victim was taken to the Bicêtre Hospital, where he was interviewed later on by the penitent drunkard who had so savagely attacked him. Dr. Landry, who was standing near the bed, asked the latter, "Should you like to give him back his ears?" "Certainly," replied the penitent. "Then," said the doctor, "let me cut out a couple of small slips of flesh from your arm, and the thing is done." To this the man readily assented, and M. Landry is reported to have thereupon performed a plastic operation with complete success. This story is a good one, and is within the compass of modern surgery, although to the outside world it must savour somewhat of the Baron Munchausen style of anecdote.

Dublin Hygiene.

In a letter to the Dublin papers Dr. Roche, Professor of Hygiene, has urged that the excessive death-rate of Dublin, and the questions of main drainage, subsoil drainage, and the various other panaceas for the remedying of the existing state of things shall be investigated by a Royal Commission. The suggestion, though not encouraged by some of the Dublin papers, seems to be the only one of a practical character which can satisfy the citizens or reconcile them to the expenditure of the enormous sums of money required. The disputants are at present the Public Health Department of the Corporation on the one side and the amateur sanitarians on the other. Be it said with respect, the citizens have not complete confidence in the statements, opinions, or arguments of either party. Where, then, when the expenditure of nearly a million of the citizens' money is involved, is wisdom to be found? Only, we apprehend, in the judgment of a totally disinterested and unpledged Commission such as Dr. Roche advocates. It will cost, no doubt, some hundreds of pounds, but that matters very little to those who speak with so much complacency of the expenditure of hundreds of thousands. The Commission will no doubt recommend terrifically drastic procedures, as all such Commissions do, but at least the citizens will have some trustworthy information to guide them before they embark upon the appalling outlay which is now declared to be necessary.

Sentimentalism and the Proposed Institute.

The proposed foundation at Chelsea of the Institute for scientific research has given rise to a chorus of condemnation on the part of the sentimentalists. One reverend gentleman has written to the public papers pointing out the danger that flies will carry off deadly bacilli from the new laboratory and scatter them broadcast through the neighbourhood. Several ladies write to protest against the erection of this "new torture chamber." They anticipate the repetition at their very doors "of all the horrors of the Pasteurian system and any other form of so-called 'scientific' research which suggests itself to the imagination of a handful of 'men' who regard the sentiment of pity as one unworthy their consideration." Of course, to be consistently logical, all these good sentimentalists, who are so eager to denounce the inhuman brutality of vivisectionists, must decline to avail themselves of any advantages that have resulted from that practice. In this way they would cut themselves off at once and entirely from the whole range of modern surgery, whose foundations were laid by Pasteur. Scientific medicine, moreover, owes a great deal to vivisection, but the sentimentalists appear to think nothing of such trifles when compared with the comfort of a few dogs and guinea-pigs.

The Indian Medical Congress.

AT a meeting of the Council of the Calcutta Medical Society, on January 24th last, it was decided that an Indian Medical Congress should be held in Calcutta at the beginning of January, 1895. It was also decided that in each province local secretaries, native as well as European, should be asked to co-operate with the Calcutta secretaries, and it was further decided that the sections into which the Congress should be divided should be—(1) Medicine, including pathology; (2) Surgery; (3) Obstetrics and Diseases of Women and Children; (4) Public Health; (5) Medico-legal Medicine and allied subjects. Medical men practising in every part of the world, but especially those in India and the East, will be welcomed by the promoters of the Congress.

Soap and Water.

SOME interesting facts about soap were lately given at the London Institute by Professor Vivian Lewes in the course of a discourse on the "Chemistry of Cleaning." The lecturer stated his opinion that there was nothing better than good bar soap, provided a proper price be paid for it. The British manufacturer, being the most accommodating individual that ever stepped, would provide it almost at any price, but it was pretty plain he would not do so at the expense of his own pocket. A similar principle, by the way, is capable of a widespread application in these days of advertising. The learned professor stated that by the addition of certain chemicals soap can be made hard enough to sell, although it retains 50 per cent. of water. In fact, one man of science had declared that the aim of the average soap maker was to render water sufficiently stiff to be able to stamp it into tablets. In speaking of the wasteful action of hard water on soap, Professor Lewes mentioned that at Glasgow the new Loch Katrine water supply had saved the city several thousands a year in soap. To this statement he added the amusing remark—"and mind you, Glasgow is not a place where they waste soap."

Alleged Bribe of a Sanitary Inspector.

A MEDICAL Officer of Health, however zealous and and efficient, is very much in the hands of his inspectors. If his staff be untrustworthy, then all his inquiries, his prosecutions, and his attempted reforms will be fruitless. From this point of view, then, it is gratifying to hear of the prosecution of a Lambeth Road builder for attempting to bribe a Battersea sanitary inspector. The latter alleges that the defendant was served by him with notices to carry out certain alterations, and on one occasion asked for his address, which he gave at the vestry office. Shortly afterwards a letter arrived there addressed to him and enclosing 5s. The defendant was committed for trial. This case points to the existence of that proper spirit among the administrative staff without which London and other large cities can never hope to attain to anything like a sound sanitary government.

A Simple Mixture.

THE following announcement occurred in a recent leading article in the *Bradford Observer*: "A very interesting case of professional trades-unionism was decided in the Court of Appeal last week. A medical man named Allinson moved against the *Medical Defence Union, which had struck his name off the list*, and *claimed to have it put on again.* To be struck off the Medical Union's list is very much like being on the blacklegs' list. It means that the dismissed medico has in some way transgressed the code of the profession." The italics are ours. Our contemporary has made a funny mistake, but the confusion of names here displayed only proves again how curious are the notions which even persons who should know better are prone to disseminate in respect to matters affecting the medical profession.

The Pimlico Mystery.

WHAT is known as the "Pimlico mystery" has now been resolved into the prosecution of a so-called "medical assistant," a man aged 54, for the alleged performance of an operation for the induction of abortion upon a young girl, for whose death in consequence a midwife is now undergoing a sentence of three years' imprisonment. The new development of the case has been due to the revelations of the convicted midwife, whose evidence has materially justified the prosecution of the defendant.

THE medical staff of the Melbourne Hospital recently passed the following resolution:—"That it is desirable that an honorary anæsthetist be appointed, who shall administer anæsthetics on appointed occasions, and shall give systematic instructions in their methods of administration, and that rules be drawn up for the guidance of such officer." We trust, in the interests of the hospital, that the committee of management will accede to this request.

THE new Canon of Westminster, Wilberforce by name, is not unknown to medical men. He rejoices in being an anti-vivisectionist, anti-vaccinationist, anti-alcoholist, anti-tobacco smoker, and probably some other "antis," and one feels inclined to ask him, as Lord Esher asked Mr. Allinson, "if he has any other fancies"!

THE Council of the British Institute of Preventive Medicine, of which Sir Joseph Lister is chairman, and Sir Henry Roscoe, M.P., treasurer, have appointed Mr. Alfred Waterhouse, R.A., architect to the institute, the building of which is to be begun at once.

THE death is recorded of Dr. Robert Savile, of Nafferton, near Hull, at the age of 60.

A woman named Goomley has been arrested near Beragh (Tyrone) for the alleged poisoning of her husband. She is supposed to have administered a dose of laudanum to him in order to keep him quiet while he was under the influence of drink.

The adjourned inquest upon Dr. Cranstoun Charles was resumed on the 25th ult., and the evidence showed that death had occurred fromm orphia, two-thirds of a grain of which were found in the stomach. Signs of acute bronchitis were also present.

The Torbay Hospital is about to open an ophthalmic department in connection with the institution, and the appointment of honorary ophthalmic surgeon will be made next month. Hitherto most of the ophthalmic cases have been sent from the Hospital for treatment to Exeter.

Dr. Hughlings Jackson, F.R.S., having retired from the active list of physicians to the London Hospital, has been unanimously elected consulting physician to that institution. In consequence of this retirement a vacancy will occur on the list of physicians, which it is proposed to fill at a special meeting to-day.

The death is announced, at New Ross, co. Wexford, of one of the fathers of the profession in Ireland. Dr. Rossiter took his M.D. at the University of Edinburgh as far back as 1834, and practised for more than fifty consecutive years in the town in which he died.

It has been officially announced that no case of cholera has occurred in St. Petersburg since the 16th ult. The disease has also almost disappeared from Constantinople.

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Morrison Lectures on Insanity.—Dr. Batty Tuke delivered the fifth and last lecture of this series on Wednesday of last week. In speaking of the treatment of insanity due to over-exertion of the brain, he said that it was useless to approach the subject through the portal of psychology. So-called psychologists really knew no more about the matter than the physicians who undertook ordinary practice. The ordinary physician had to deal every day with perversion of the mental faculties; he had to treat hysterics, alcoholists, opium-eaters, so-called neurasthenics, the consumptive, the febrile, the pregnant, and endless other types in which morbid modification of psychological functions were manifested. Did a man know anything more about the workings of the component parts of the mental constitution and their attributes because he had practised more amongst the insane than the sane? He deprecated the indiscriminate use of travel, amusement, and opiates. The highest attainable rest was of the greatest use. In conclusion, Dr. Tuke said that if incipient cases of insanity could be treated properly in ordinary hospitals, many cures now impossible might result, and the patients relieved from the stigma of having been in an asylum. Wards should be set apart in each of our general hospitals for this purpose.

University of Edinburgh.—Among the honorary degrees offered to gentlemen at the spring graduation we find the names of Sir Dietrick Brandis, Ph.D., K.C.I.E., &c.; Mr. W. H. Gaskell, M.D. (Camb.), F.R.S., Lecturer on Physiology, University of Cambridge; Professor William James, University of Harvard; Mr. James Alexander Russell, M.A., M.B., B.Sc., Lord Provost of Edinburgh; Mr. George Wilson, M.A., M.D. (Edin.), Medical Officer of Health, Mid-Warwick, who have been offered the degree of LL.D.

The Microphone in Medicine.—At the *conversazione* held in the Faculty Hall, Glasgow, on Friday, the 23rd ult., Dr. Macintyre exhibited a number of new electrical instruments as well as some interesting micro-phonographic records. With the perfection to which the instrument has now been brought, the phonograph is not unlikely soon to take its place as an instrument of instruction in medical teaching. Dr. Macintyre was able to demonstrate a number of cough sounds; varieties of hoarseness due to different pathological conditions; and he has been able by special recording arrangements to register the heart sounds. Doubtless stethoscopic sounds offer the greatest difficulty of all, but by properly arranged conducting apparatus fairly good records have been obtained of different sounds heard within the chest. Dr. Macintyre also exhibited a number of microphones, some of the ordinary varieties, and others adapted specially for medical purposes. The principal one of interest was an instrument enabling a number of students to listen to the sounds of the body at the same time, and also to transmit these sounds to a distance. Dr. Macintyre showed how these might be utilised so that students in a class-room of a medical school could hear the chest sounds of a patient in an hospital at a distance. The slight disadvantages of the apparatus at present are that the instrument is extremely sensitive, so other sounds may sometimes be heard at the same time, and a little alteration in the quality of the sound as heard through the ordinary stethoscope. The apparatus consisted of a microphone specially adapted for application to the human body, induction coil to transmit sounds to a distance, small battery and telephone receivers, of which the Ader has been found to be the best. By such means it will doubtless be possible to fit up our schools so that large numbers of students may be trained at the same time to appreciate the sounds heard within the body, even though the patient may be at a considerable distance, and with improvements in the recording apparatus of the phonograph to take permanent records of the same.

THE LAW REGARDING OATHS.

Complaints are frequenely made to us by correspondents of the difficulties thrown in their way in Courts of Law, especially in Coroners' Courts, County Courts, and before Commissioners of Oaths, on declining to kiss the grimy book in taking the oath. Strange as it may seem, the Presiding Officer is often not cognisant of the existence of the Act, or is under the impression that it is a declaration and not an oath to which the Act applies. The medical witness is then asked if he has a copy of the Act or an abstract with him, or anything to show the Court in support of his contention that he is privileged to affirm, or desires to swear with uplifted hand after the Scotch manner. Medical men do not usually carry Acts of Parliament about with them, and rather than be browbeaten in this matter they take an aerial kiss at the book and pocket their conscience. A suggestion has been made by a correspondent, whose opinion we highly value, that we should print the Act referred to for the benefit of our readers, and we have much pleasure in acceding thereto. We may add, to save mutilating the journal in which this appears, that we have printed a large number of copies of this Act on thin paper, so that it may be folded and carried in the pocket-book, and have instructed our publishers to forward same free of charge to any of our readers on receipt of a halfpenny stamp to cover postage.

CHAPTER 46.

An Act to Amend the Law as to Oaths.

A.D. 1888.

[24th December, 1888.]

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

When affirmation may be made instead of oath.

1. Every person upon objecting to being sworn, and stating, as the ground of such objection, either that he has no religious belief, or that the taking of an oath is contrary to his religious belief, shall be permitted to make his solemn affirmation instead of taking an oath in all places and for all purposes where an oath is or shall be required by law, which affirmation shall be of the same force and effect as if he had taken the oath; and if any person making such affirmation shall wilfully, falsely, and corruptly affirm any matter or thing which, if deposed on oath, would have amounted to wilful and corrupt perjury, he shall be liable to prosecution, indictment, sentence, and punishment in all respects as if he had committed wilful and corrupt perjury.

Form of Affirmation.

2. Every such affirmation shall be as follows:

"I, A.B., do solemnly, sincerely, and truly declare and affirm," and then proceed with the words of the oath prescribed by law, omitting any words of imprecation or calling to witness.

Validity of oath not affected by absence of religious belief.

3. Where an oath has been duly administered and taken, the fact that the person to whom the same was administered had, at the time of taking such oath, no religious belief, shall not for any purpose affect the validity of such oath.

Form of affirmation in writing.

4. Every affirmation in writing shall commence "I, ________, of ________, do solemnly and sincerely affirm," and the form in lieu of jurat shall be "Affirmed at ________ this ________ day of ________, 18___. Before me."

Swearing with uplifted hand.

5. If any person to whom an oath is administered desires to swear with uplifted hand, in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question.

Repeal.

6. The Acts mentioned in the schedule to this Act are hereby repealed to the extent in the third column of the schedule mentioned.

Short title.

7. This Act may be cited as the Oaths Act, 1888.

SCHEDULE.

Session and Chapter.	Title.	Extent of Repeal.
17 & 18 Vict. c. 125.	The Common Law Procedure Act, 1854.	Section twenty.
19 & 20 Vict. c. 102.	The Common Law Procedure Amendment Act (Ireland), 1856.	Sections twenty-three and twenty-four.
24 & 25 Vict. c. 66.	An Act to give relief to persons who may refuse or be unwilling, from alleged conscientious motives, to be sworn in criminal proceedings.	The entire Act.
28 & 29 Vict. c. 9.	The Affirmation (Scotland) Act, 1865.	The entire Act.
30 & 31 Vict. c. 35.	An Act to remove some defects in the administration of the Criminal Law.	Section eight.
31 & 32 Vict. c. 39.	The Jurors Affirmation (Scotland) Act, 1868.	The entire Act.
31 & 32 Vict. c. 75.	The Juries Act (Ireland), 1868.	Section three.
32 & 33 Vict. c. 68.	The Evidence Further Amendment Act, 1869.	Section four.
33 & 34 Vict. c. 49.	The Evidence Amendment Act, 1870.	The entire Act.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

ALLEGED DISCOVERY OF AN ANTIDOTE TO MORPHINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In answer to your editorial request (*Medical Press*, Feb. 21), I beg to bring to your notice the following facts as regards the alleged discovery of permanganate of potash as an antidote to morphia. I brought out a series of articles in the *Chemist and Druggist* of 1877, *vide* page 55, dealing with the quantitative estimation of various substances by means of an acid solution of permanganate of potash. My method was distinct from any other method in several respects. In the first place it was a *weak* decimal solution, whereby, contrary to what might be found in Gmelin's Chemistry of that date, "that permanganate of potash had no reaction on morphia," I was enabled to establish what I have always considered the most elegant quantitative test for the estimation of morphia, or mixtures of morphine when mixed with narcotine. Again, I found dilution determined differences, so that I introduced a short manipulative process of regular delivery, &c., and disregarded the teachings of equivalents in their exactitude.

For the convenience of those who might use my method I finally brought out a carefully made 1 per cent. permanganate of potash solution more than ten years ago, and on the label, of which I send you a copy, are these words: "As an *antidote* to opium, morphia, and laudanum, the *diluted* solution may be administered in doses of a wineglassful." The subsequent change of the strength of the official solution of permanganate of potash rendered my solution unnecessary, and as my method has become one of great importance since 1890 for the estimation of food-stuffs, and is especially well known amongst millers for the estimation of albuminoids in flour, I have earnestly endeavoured to compel pharmacists to supply a *standardised* solution of permanganate of potash according to the requirements of the Pharmacopœia, and hope that medical men will remember that we have a very valuable ally in such an official solution, which ought to be distinguished from all coloured disinfectants. The breaking up of morphia by permanganate of potash seems a very insignificant factor in my system of rapid estimation of food-stuffs. As regards the claims made recently for permanganate of potash as an antidote to strychnia and cyanides, I remember those substances with atropine did not sensibly affect my test, whereas veratrine and aconitine did; solutions of the latter have for some months been carefully prepared by Messrs. Hopkins and Williams awaiting my investigation. As regards the irrigation of the whole alimentary canal with permanganate solution, as a general antidote in some cases of poisoning by natural and artificial alkaloids, I have antipyrine and similar salts in view, which you will find mentioned in my work, or again for cholera, dysentery, &c., I have long foreseen that from a forensic point of view we want the whole history of the oxidation products of alkaloids amongst our immediate desiderata. My work must remain amongst the ephemeral literature at present; meanwhile, Dr. William Moore has apparently given the first demonstration of permanganate of potash as an antidote to morphia, to which we must add our verification in due season.

I am, Sir, yours, &c.,
J. Barker Smith, L.R.C.P.Lond.

Feb. 21, 1894.

BUSYBODIES AGAIN

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—There does not happen to be a body comparable to that of the General Medical Council, in the Church of England, whose duties would include dealing with clerical quacks who turn their churches—or proprietary chapels—into lecture halls every Sunday for the purpose of attracting congregations and swelling the collections. If this were the case, there is no doubt that one of this community in the neighbourhood of St. Marylebone would soon find himself adjudged guilty of "infamous conduct in a professional respect," and have his name removed from the roll of the English clergy. But of his lecture-hall antics in the pulpit nothing more need be said here. Nor need anything be said of the manner in which he sees fit to "puff" his books or leaflets among his congregation. My reason, however, for calling attention to this "Rev. Mr. Puff," as he was described once by a Sunday paper, is to point to his latest effort to obtain a gratuitous advertisement. He sent last week a communication to the metropolitan press, which appeared in two only of the morning papers, in which he attempted to lecture the public on the dangers of establishing the British Institute of Preventive Medicine in Chelsea. I forbear to traverse his so-called arguments, for they are nonsense from beginning to end; they, moreover so clearly display his utter want of knowledge of the subject discussed that the wonder is that the editors of the journals in question were ever deluded into publishing them.

I am, Sir, yours, &c.,
Anti-Humbug.

◆

THE CONJOINT EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS, IRELAND, AND APOTHECARIES' HALL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—An article under the above heading appears in your last issue, and as it contains several inaccuracies, I am confident that you will permit me, personally alluded to in it, and also conversant with every detail, to point these out and to state the actual facts of the case.

In the first instance I can declare positively that neither the College of Physicians as a body, nor the Fellows individually, had anything to do with the motion recently made in the Council of the College of Surgeons to reconsider the conjunction of the latter body with the Apothecaries. We doubtless consider that conjunction derogatory, but the movement you speak of was quite unexpected by us.

The facts of the whole matter are these: Prior to May last I, in common with the other Fellows of the College of Physicians, paid no attention to the mode in which candidates were admitted to the examinations conducted by the Conjoint Board of the College of Surgeons and Apothecaries; but a few days before the meeting in May last of the General Medical Council a copy of the new regulations as to education and examination under the five years' scheme, drawn up by these two bodies, was placed in my hands, from which it appeared that no less than five of the subjects of education required by the General Medical Council from all candidates were omitted therefrom.

As these omissions had escaped the notice of the Education Committee of the General Medical Council, I in my place in the Council called attention to this oversight, with the result that the Committee reported to the Council that the curriculum of the College of Surgeons, Ireland, and the Apothecaries "was not in accordance with the requirements of the Council." It must be borne in mind that these "requirements" apply to all Universities and Licensing Bodies in the Kingdom.

In the autumn of that year (1893) I was a member of the Conference which you alluded to as convened to endeavour to settle matters amicably between the Colleges. Four subjects were to be discussed:—

1. Where was the office of the Committee of Management of the Colleges of Physicians and Surgeons to be located?
2. Certain questions relative to the school of the College of Surgeons.
3. The defective curriculum of the College of Surgeons and Apothecaries.
4. The question of the reduction of £5 5s. made by the College of Surgeons for their diploma in favour of candidates in their scheme with the Apothecaries.

Of these the first was easily settled; the second was withdrawn without discussion by the Representative of the College of Surgeons; the fourth was not discussed at all, the Representative of the College of Physicians not pressing the matter. The third alone was fully discussed. It was moved by myself, "That the requirements of the General Medical Council should be complied with," and though I pointed out that it was not a question between the Colleges, but between the College of Surgeons and Apothecaries on the one hand, and the General Medical Council on the other, and that they certainly would be enforced, the delegates of the College of Surgeons, nevertheless, unanimously voted against the resolution, and the motion fell to the ground, These facts hardly admit of your statement "that every suggestion of the Surgeons was received by the Physicians with the customary *non possumus*" being considered accurate.

The date of the meeting of the General Medical Council was approaching (November, 1893), but the discussion which had taken place at the May meeting, and letters which had appeared in the medical journals had attracted attention, and complaints from students and statements from recently qualified practitioners were made to me, which led me to the conclusion that a regular system was being carried on by means of which the diploma of the College of Surgeons and the license of the Apothecaries' Company was granted to candidates who evaded a complete examination in important subjects of education, and in some cases without any examination whatever in physiology. The investigation of the cases mentioned to me was tedious and difficult, and I was unable to formulate the results of my investigation in time to lay it formally before the Council in November, but I moved a resolution to the effect "that the irregularities I complained of be referred to the Education Committee for investigation and report." Sir Philip Smyly, the Representative of the College of Surgeons, intervened and asked that the matter be postponed. To this, in deference to his wish, I at once acceded, and Sir Wm. Turner having suggested that it would be better to proceed by memorial. I on my return to Dublin moved in the College of Physicians that this course be adopted. A memorial has, therefore, been drawn up by the College, has been before the Executive Committee of the General Medical Council, and copies of it have been ordered to be forwarded to the College of Surgeons and Apothecaries' Hall. As the question is *sub judice*, and as it will be discussed fully at the next meeting of the General Medical Council, I shall say no more on the subject. But the foregoing facts show conclusively that your statement that "the general accusation made by the Representative of the College of Physicians of curriculum and examination" "has never been formulated or specified" is quite incorrect.

No doubt the same document which announced that the diploma of the College of Surgeons and Apothecaries' Licence could be obtained on a defective curriculum also intimated that the College of Surgeons would charge £5 5s. less for its diploma to candidates under its conjunction with the Apothecaries than it did to those under their conjunction with the College of Physicians, but though the College of Physicians deemed this a most improper step for the College of Surgeons to take, no notice of it has been taken by the College of Physicians beyond a letter addressed to the College of Surgeons, expressing their surprise at the step. Nor have I, in the General Medical Council or elsewhere, ever spoken of the matter, and I emphatically deny that the reduction of fee by the College of Surgeon was the cause of my action. I have been influenced solely by a desire to see that the standard of medical education in Ireland be maintained, so that it shall not be possible for any one to allege that medical education in Ireland is inferior to that required in either England or Scotland for the obtaining of medical qualifications.

I must also point out that you are quite mistaken in stating that "the General Medical Council was induced by the College of Physicians to fulminate a threat that it would extinguish the Apothecaries' Hall conjunction" if it did not conform to the "Requirements" of the Council in regard of medical education. I was absolutely ignorant of the nature of the report of the Education Committee till it was presented in print to the Council and the resolution of the Council to which you refer was passed on the last day of the meeting of the Council, when I had already returned to Dublin, and I was not even aware that the subject had been taken up till I received a copy of the minutes two days subsequently. Had I the power to influence the Council, which I certainly have not, it was impossible for me to have done so on this occasion.

I am Sir, yours, &c.,
Lombe Atthill, M.D.
Representative of the Royal College of Physicians, Ireland on the General Medical Council.

March 1st, 1894.

THE FLAP-SPLITTING OPERATION (COLLIS'S).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

Sir,—I am persuaded it is not generally known by the profession that the plan of flap splitting (in order to obtain a larger surface for an Irish union, and of late years associated with the name of Mr. Lawson Tait) was originally designed and carried out by a surgeon, Mr. Maurice Collis, of the Meath Hospital, Dublin. In the *Dublin Quarterly Journal* for May, 1861, he published a full description of this plan of operation as applied for the cure of vesico-vaginal fistula (and it is evidently an adaptation of this plan to perinæorraphy that Mr. Tait is usually credited with). In the preface to Vol. ii, July to December of *Braithwaite's Retrospect*, 1861, the following occurs (alluding to Collis's operation):—"Why should not the same principle be carried out in numerous other operations of a similar kind, such as cleft palate, hare-lip, and *ruptured perinæum?*" Though late in the day I wish to claim the honour of originating the "flap-splitting operation" for an Irishman, the late Mr. Maurice Collis, and am inclined to think it will be news to a large number of both English and American surgeons.

I am, Sir, yours, &c.,
Alexander Duke.

Cheltenham, March 3rd.

THE MECHANICAL TREATMENT OF PHTHISIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—An article with this title was recently (Jan. 24th) published in the Medical Press and Circular, and I find it suggestive of some remarks. Mr. Noble Smith, F.R.C.S.Edin. (the author), whilst describing the utility of a certain appliance of his own for relieving a weak chest of the weight of the arms, and so assisting to improve the vital capacity of the lungs at their apices, makes no allusion to another sort of adjuvant of probable value which might be resorted to for the same purpose, viz., a pair of crutches, of full length, to be used for frequent exercise. Placing the feet together, the body might be swung forward at every step, and the walking kept up for a considerable time. The effects would be to take the weight of the arms off the chest, to raise and open the shoulders, and to straighten the spine by the force of the swing.

In this connection, another matter occurs to me—the advantage that might be got by cycle-riding exercise if cycles were adapted (as perhaps they might be) to this special purpose. I think bicycles, as they are, are hideous things. A man riding on a point, a line, like a pyramid upside down, its base in the air, and presenting to view an attitude embracing perhaps all the bad points in figure possible at one and the same time. There are the cycle stoop, the rounded shoulder, the arms fixed down on the chest, depressing and flattening it, so that the hands may be devoted to the cross-bar in front for steering. Bad enough all this for the healthy chest; could anything be worse for the weak one? And yet all this might be easily changed, and the cycle become wholesome, conducing to a good figure, and affording an excellent means of exercising and developing ill-formed chests.

What must be done is to place the steering-bar *behind* the rider instead of *before* him. By this change all the evils would be turned into advantages: the rider's hands must then do the steering behind his back, like the steersman of a row-boat. His chest would be opened, his shoulders thrown back, and he must perforce sit upright like a man on horseback instead of grovelling forward like a rag-picker at work in the gutter.

Thus, cycling might be cured of some great and unwholesome faults, and instead of being a danger to the sound, might actually be made a valuable exercise for the weak and ill-formed. But this arrangement might not be applicable to the *bi*cycle because the rider could hardly mount or dismount without his hands on the steerage. It could, however, be applied to the *tri*cycle machine, which stands of itself, a much better-looking affair, a pyramid standing on its base. By this change in the steering place, I think tricycle exercise might become a valuable means of improving and restoring narrow chests, and indirectly of increasing the vital capacity of the lungs, whilst the healthy rider would cut a much better figure and avoid the injury which the present style seems calculated to produce.

I am, Sir, yours, &c.,

J. E. HUXLEY.

Maidstone, Feb., 1894.

MEDICAL SOCIETY OF LONDON.

THE first business on Monday evening last (March 5th) was that incidental to the annual meeting. The official nominations of officers for the ensuing year were approved, and this business having been disposed of,

Dr. Lewis Jones read a paper on "The Electrical Treatment of Infantile Paralysis," which we hope to publish in full in our next issue.

In the discussion that followed, most of the speakers agreed on the benefit to be derived from persistence in the electrical treatment, and Dr. Cagney suggested that many cases of supposed poliomyelitis were really instances of peripheral neuritis in children.

Dr. W. Wallace Ord and Mr. H. F. Waterhouse contributed notes of the case of "Cure of Tubercular Meningitis by Drainage" in a girl, æt. 5, who entered hospital with all the characteristic symptoms of tubercular meningitis. She had double optic neuritis, the peculiar cry and well marked *tâche cérébrale*. Symptoms of intra-cranial pressure having made their appearance, they trephined through the cerebellar fossa of the occipital bone, letting out a small quantity of fluid. They closed the wound, leaving in a drainage tube, and the child recovered and was shown at the meeting.

Mr. Walsham advocated making the opening through the lamina of one of the cervical vertebræ, and referred to a case in which he had operated thus, the child dying soon after, whereupon it was made manifest that the case was not one of tubercular meningitis at all.

Dr. Pasteur mentioned that at Middlesex they were in the habit of relieving intra-cranial pressure by an opening in the lumbar region, but the results had not been satisfactory, possibly because the services of the surgeons are not usually requisitioned until the patient has become comatose.

Mr. Battle appealed to the physicians not to wait until coma had been established, a condition which precluded all hope of success.

Mr. Bidwell observed that he had found calcified tubercles in children who had died without symptoms of tubercular meningitis, though there was a history of a previous attack. He pointed out that the so-called tubercular meningitis was often middle-ear disease.

Mr. Waterhouse discussed the choice of the site of operation, and expressed the hope that this line of treatment would be further extended in the immediate future.

Dr. Ord pointed out that the orifice of communication of the sub-arachnoid space with the spinal canal was often blocked by inflammation in such cases. That was one very good reason for operating through the occipital bone.

IRISH STUDENTS IN EMEUTE.

THE students in attendance in the School of the Royal College of Surgeons in Ireland have organised themselves in revolt against an order of the Committee of Management for the Conjoint Examinations with the College of Physicians, which declares that the Examiners shall have authority to send back a rejected candidate not only to re-examination in the same subject, but to further courses of study thereon, which means, of course, great delay—possibly the losing of a year—and probably the payment of an additional fee. We understand that the students have formed a permanent Association and have held meetings and prepared a memorial which is on its way for presentation to the Council of the College of Surgeons. This is the right way of doing business. Students who provide the sinews of war for both Professors and Colleges possess an unquestionable moral right to make representations to the powers that be upon matters which affect them, and we are quite sure that, so long as those representations are made calmly and logically, both the Colleges and the Professors will be not only willing, but glad to hear and consider them. The students' organisation ought, for its own sake, to sternly suppress any demonstration of unruliness or insubordination which would at once put their propositions outside the pale of favourable consideration by the authorities.

There seems to be a mistake about this particular rule. It was originally adopted as a recommendation by the General Medical Council, and was simply put in the Regulations by the Committee of Management, as in duty bound. It was not, however, enforced, we believe, in more than two instances since the opening of the Conjoint Examinations in 1887. Quite recently the Visitors from the General Medical Council have hinted a censure upon the Conjoint Committee with the Apothecaries' Hall because they did not remit rejected candidates to study, and, inquiries being then made, the Physicians' Committee has thought it necessary to resurrect the regulation and give notice of it, though we have no reason to suppose that it is intended to enforce it any more than it has ever been enforced.

So far as we understand the feeling of the students, we must sympathise with them. We think that the answering of a candidate should be phenomenally bad to justify his being put back for a year and subjected to a fine. Moreover, it seems reasonable to say that the function of an Examiner is to stand in the portal and to refuse to allow anyone to pass who does not show a standard knowledge of his work, but we do not see that it is any part of his business to interfere as to the method by which that knowledge shall be acquired. Furthermore, it seems to be an unsound principle to put into the hands of Examiners, who are for the most part teachers of the subject in which they examine, the power to send back candidates, possibly to their own classes, and to the payment of an additional fee. In our opinion the original regulation of the General Medical Council was wrong, and we see no special reason for its resuscitation.

Special Articles.

WOMEN AND ATHLETICS.

[BY A LADY.]

IN every community there are to be found large numbers of people who raise their voices warningly against all forms of violent athletics for women. Doctors of the old school, medical students who rejoice in the dangerous possession of "a little" knowledge, men and women who were brought up in the days when croquet was considered the limit of what was possible or advisable for the softer sex, declare that rowing, riding long distances on a bicycle or tricycle, and above all, the exercises of the gymnasium, are "most dangerous," and sure to result in ultimate injury. Woman was not intended to jump, climb, run, or exert herself in any violent way; and even though no harm may be actually apparent, it is certainly going on, and will come out sooner or later.

It is strange that these medical theorists cannot apply the knowledge of human anatomy that it is presumed they possess a little more accurately. If women were intended to live a life that comprehended no active exercise, for what reason has Providence furnished them with muscles evidently intended for violent exertion The feminine muscular system is, I am sorry to say, but quarter-developed in nineteen cases out of twenty: that, however, is the fault of the many blunders in dress or hygiene committed by our social system, [not the fault of the original plan, which—as witness the often-quoted sculptures of Greece—is, indeed, a grand one. When we realise the exquisite combination of beauty and strength which is possible for the female form, and compare it with the development possessed by the average society girl, it is impossible not to feel regret. Where, in the modern figure, is the splendid supple curve of back and side that comes from the proper training of the great muscles attached to the spine—where the sweeping rounded *deltoid* that gives such grace to the arm—where the firm elastic waist and springy carriage that are due to abdominal muscles unatrophied and unconfined in steel? You may find them in our gymnasia at the end of a term; or, occasionally, in the person of some accomplished oarswoman or swimmer; but in the large number of cases, the weak backs and waists, lean straight arms, and unshapely necks possessed by women would really lead the casual observer to conclude that athletic exercises were totally impossible to such organisations.

Now, the outcry of "danger" that has in so many cases arisen, with regard to gymnastics, cycling, and the like, is entirely due, in the first place, to such weakly-developed women and girls as the above attempting to start from the same ground as the other sex; and, in the second place, to the injudicious efforts made by a few essentially delicate and feeble women, handicapped by some organic weakness, to keep up with their stronger companions. In such practices, there *is* danger. I have seen a delicate girl whose ambition far exceeded her physical powers, undertake a long trying cycle ride with companions who hardly knew what fatigue was, and as a result, find her health permanently damaged: and I have heard her case cited as an argument why a much stronger girl, in perfect physical condition, should not undertake similar excursions, although she obtained unmistakable benefit from them—such being an example of the wide-spread results of a single piece of folly. I have watched girls in the gymnasium at the beginning of a term, practising after the class was over until exhausted nature actually compelled a stop, and then retiring to the dressing-room to lie down for some time before being able to dress. I have seen novices at golf take up the game with fury, play round after round of a three mile course without stopping, and then wonder why next day brought lassitude and pains in all the limbs. It is such careless acts as these that bring discredit on healthy exercise for women, and give the alarmists ground to go upon when they declare that the gentlest exertions alone are appropriate to the softer sex.

The subject is much too large to consider in its entirety within the limits of a single article; but one form of sport may perhaps serve as an example for the rest. Take the gymnasium. Any reader who has ever gone through a course of gymnastic training will agree with the sentiment expressed by the instructor of the City of Dublin Gymnasium—"Gymnastics are the hardest work in the world"—and yet, when comparing the different experiences of four ladies' gymnasium classes, I can recall no one instance of any injury or strain. I have seen a slightly twisted ankle or wrist, or a bruise, once or twice; but such mishaps as these are amongst the accepted risks of any active exercise. Of course, all the members of a class do not take up the work with enthusiasm; but even those who do—who take a pride in performing difficult feats with ease and grace—invariably find their health, strength, *and looks*—the last an important point in feminine estimation—considerably improved.

The secret of health and safety in all such exercises for women is that which is the motto of every well-conducted gymnasium, and should also be the motto of every feminine beginner in tennis, cricket, rowing, cycling, or swimming—*festina lente*—no hurry. The muscles of the average girl beginner are weak and soft. If she attempts to do her best in any one thing at the outset, she *may* harm herself. A muscle out of condition is very easily strained or torn; a muscle, on the contrary, that has been properly developed by suitable exercise, will stand the utmost stress that the will of its owner can put upon it, with positive benefit. "Don't attempt it after you are tired," is the warning of the teacher, at the outset. "Go on trying till you cannot do it again, and then *try a little longer*," are the directions given to the pupil who has attained some degree of proficiency.

I am not writing from a medical standpoint; it is possible, I have no doubt, to prove out of books—conclusively, to all appearance—that woman was not made to indulge in athletics. It is possible, however, to prove almost anything—on paper. It used to be conclusively proved that fresh air and cooling drinks were most harmful to the fever patient; that chloroform would raise death-rates enormously all round, and that vaccination would ultimately result in transferring some of the characteristics of the cow to the human race. Practice disproved these "irrefragable" conclusions, and it is doing just the same by the old cry of "danger" in reference to feminine athletics. Is it likely, when the subject is impartially considered, that the Providence which designed the marvellous human frame, and gave to both sexes a perfect muscular system, adapted for every movement, would so order things that the legitimate use and development of this system should, for one half of the human race, be fraught with danger? Nature does nothing uselessly, and her laws are inexorable. For the neglect of any one of her gifts she inflicts penalty, as surely as night follows day. Women are only now awakening to the fact that they have been so neglecting one of the greatest of her gifts; let them look round and learn from the health of the savage what the penalties in their own case have been; and from the beauty of the ancient Greek, what the loss. If they learn this lesson and thoroughly, the twentieth century will see a race of women whose grace, beauty, and health will not only transform their own sex, but also, through their duties as mothers, regenerate the world.—Graphis.

Literature.

MURRELL'S FORENSIC MEDICINE AND TOXICOLOGY.

The "Aids to Forensic Medicine and Toxicology," by W. Murrell, M.D., F.R.C.P. (Baillière, Tindall and Cox, 1894) fills a lapsus in the valuable series of student's guides. Legal medicine is not a subject in respect of which examining boards are, as a rule, severe, but candidates are expected to have mastered the general principles, and these are succinctly set forth in the volume before us in such a way that they can be committed to memory with a minimum of trouble and in a minimum of time. The author has not contented himself with a plain, unvarnished synopsis of the facts—these, or many of them, are detailed in a sprightly, almost sarcastic, style which borders on levity. Doubtless students will welcome this departure from the traditional dry-as-dustness associated with medical jurisprudence, and to be interested in one's work is half the battle. That the little book will prove a success no one who has conned its pages will for a moment doubt, since those for whose sake it was written cannot fail to appreciate its ante-examination merits.
